| <b>IEHG Publication S-401 .....</b>                                               | <b>i</b> |
| <b>1 Overview .....</b>                                                           | <b>0</b> |
| 1.1 Preface.....                                                                  | 0        |
| 1.1.1 Background .....                                                            | 0        |
| 1.2 S-401 Annex A; Data Classification and Encoding Guide - Metadata .....        | 1        |
| 1.3 Terms, definitions and abbreviations .....                                    | 1        |
| 1.3.1 Terms and definitions.....                                                  | 1        |
| 1.3.2 Abbreviations .....                                                         | 1        |
| 1.4 Use of language.....                                                          | 2        |
| 1.5 Maintenance .....                                                             | 2        |
| <b>2 General .....</b>                                                            | <b>2</b> |
| 2.1 Feature types.....                                                            | 2        |
| 2.1.1 Multiple features.....                                                      | 2        |
| 2.2 Information types .....                                                       | 3        |
| 2.3 Geometric primitives .....                                                    | 3        |
| 2.3.1 Capture density guideline .....                                             | 3        |
| 2.4 Attributes.....                                                               | 4        |
| 2.4.1 Multiplicity.....                                                           | 4        |
| 2.4.2 Simple attribute types .....                                                | 4        |
| 2.4.3 Mandatory and conditional attributes .....                                  | 6        |
| 2.4.4 Missing attribute values .....                                              | 6        |
| 2.4.5 Portrayal feature attributes.....                                           | 7        |
| 2.4.5.1 ECDIS “system” (portrayal) attributes.....                                | 7        |
| 2.4.6 Textual information .....                                                   | 8        |
| 2.4.7 Spatial attribute types .....                                               | 8        |
| 2.4.8 Dates.....                                                                  | 9        |
| 2.4.8.1 Seasonal features.....                                                    | 10       |
| 2.4.9 Times .....                                                                 | 10       |
| 2.4.9.1 Schedules .....                                                           | 11       |
| 2.4.10 Colours and colour patterns.....                                           | 11       |
| 2.4.11 Radar conspicuous features .....                                           | 12       |
| 2.4.12 Attributes referencing IENC support files.....                             | 12       |
| 2.4.12.1 Reference to textual IENC support files .....                            | 13       |
| 2.4.12.2 Reference to pictorial IENC support files.....                           | 13       |
| 2.4.13 UN Location Code.....                                                      | 14       |
| 2.4.14 Interoperability Identifier.....                                           | 14       |
| 2.5 Datasets.....                                                                 | 15       |
| 2.5.1 IENC data coverage.....                                                     | 15       |
| 2.5.1.1 Skin of the Earth .....                                                   | 15       |
| 2.5.2 Discovery metadata .....                                                    | 15       |
| 2.5.3 Minimal depiction areas .....                                               | 15       |
| 2.5.3.1 Wide blank areas .....                                                    | 15       |
| 2.5.3.2 Simplified or minimum depiction areas.....                                | 16       |
| 2.5.4 Units .....                                                                 | 16       |
| 2.5.5 Seamless IENC coverage.....                                                 | 16       |
| 2.5.6 Feature Object Identifiers.....                                             | 17       |
| 2.5.7 Heights and elevations.....                                                 | 17       |
| 2.5.8 Geographic names.....                                                       | 18       |
| 2.5.8.1 Text placement .....                                                      | 20       |
| 2.5.9 Sample scale minimum policy.....                                            | 21       |
| 2.5.10 Masking.....                                                               | 22       |
| 2.5.11 Collection Features Extending Beyond Cell Boundaries .....                 | 26       |
| 2.6 Description of table format for S-401 meta, geo and information features..... | 27       |
| 2.7 Inland specific General Guidance.....                                         | 29       |
| 2.7.1 Minimum content of an IENC .....                                            | 29       |
| 2.7.2 Source Indication .....                                                     | 29       |

|          |                                                                |     |
|----------|----------------------------------------------------------------|-----|
| 2.7.3    | Numeric precision .....                                        | 29  |
| 2.7.4    | Assigning approximate positions .....                          | 29  |
| 2.7.5    | Legal ECDIS .....                                              | 29  |
| 2.7.6    | Collection features extending beyond cell boundaries .....     | 30  |
| 3        | Metadata Features .....                                        | 31  |
| 3.1      | Horizontal uncertainty .....                                   | 31  |
| 3.2      | Vertical uncertainty .....                                     | 31  |
| 3.3      | Hierarchy of metadata .....                                    | 32  |
| 3.4      | Quality of non-bathymetric data .....                          | 33  |
| 3.4.1    | Quality of non-bathymetric data .....                          | 35  |
| 3.5      | Data coverage .....                                            | 36  |
| 3.5.1    | Coverage .....                                                 | 38  |
| 3.6      | Navigational system of marks .....                             | 41  |
| 3.7      | Local direction of buoyage .....                               | 44  |
| 3.7.1    | Local direction of buoyage .....                               | 46  |
| 3.8      | Quality of bathymetric data .....                              | 47  |
| 3.8.1    | Quality, reliability and uncertainty of bathymetric data ..... | 50  |
| 3.8.1.1  | Temporal variation .....                                       | 54  |
| 3.8.1.2  | Feature detection .....                                        | 54  |
| 3.8.1.3  | Sounding uncertainty .....                                     | 55  |
| 3.9      | Sounding Datum .....                                           | 56  |
| 3.10     | Vertical datum of data .....                                   | 60  |
| 3.10.1   | Vertical datum .....                                           | 62  |
| 3.11     | Quality of survey .....                                        | 63  |
| 3.11.1   | Survey reliability and source of bathymetric data .....        | 65  |
| 3.12     | Update information .....                                       | 68  |
| 4        | Geo Features – Magnetic Data .....                             | 71  |
| 4.1      | Magnetic variation .....                                       | 71  |
| 4.1.1    | Magnetic variation .....                                       | 72  |
| 5        | Geo Features – Natural Features .....                          | 74  |
| 5.1      | Cliffs .....                                                   | 74  |
| 5.2      | Cuttings and embankments .....                                 | 75  |
| 5.3      | Coastline .....                                                | 76  |
| 5.3.1    | Coastline .....                                                | 78  |
| 5.3.2    | Natural coastline .....                                        | 79  |
| 5.4      | Land area .....                                                | 81  |
| 5.4.1    | Land area .....                                                | 82  |
| 5.4.2    | Rocks which do not cover (islets) .....                        | 83  |
| 5.5      | Land elevation .....                                           | 84  |
| 5.6      | River .....                                                    | 87  |
| 5.6.1    | Rivers .....                                                   | 89  |
| 5.7      | Lake .....                                                     | 90  |
| 5.8      | Land region .....                                              | 93  |
| 5.8.1    | Natural sceneries .....                                        | 95  |
| 5.8.1.1  | Marsh .....                                                    | 96  |
| 5.8.1.2  | Salt pans .....                                                | 96  |
| 5.8.1.3  | Lava flow .....                                                | 96  |
| 5.9      | Vegetation .....                                               | 97  |
| 5.9.1    | Vegetation .....                                               | 99  |
| 5.10     | Sloping ground .....                                           | 100 |
| 5.10.1   | Sloping ground .....                                           | 102 |
| 5.10.1.1 | Dunes, sand hills .....                                        | 102 |
| 5.11     | Slope topline .....                                            | 104 |
| 5.15.1   | Slope topline .....                                            | 106 |
| 5.12     | Tideway .....                                                  | 108 |
| 5.12.1   | Tideways .....                                                 | 109 |
| 6        | Geo Features – Cultural Features .....                         | 111 |

# 1 Overview

## 1.1 Preface

The “Data Classification and Encoding Guide” has been developed to provide consistent, standardized instructions for encoding S-100 compliant IENC data. This document has been laid out, as far as possible, along the lines of the IHO publication S-4, Part B “Chart Specifications of the IHO – Medium and Large-Scale National and International (INT) Charts”.

The purpose of the Data Classification and Encoding Guide is to facilitate S-401 encoding to meet IEHG standards for the proper display of IENC in an Inland ECDIS or ECS. The document describes how to encode information that the cartographer considers relevant to an IENC. The content of an IENC is at the discretion of the producer provided that the conventions described within this document are followed.

The entire S-100 Standard is available at the following web site, <https://iho.int/>. The S-401 IENC Product Specification is available at the following web sites, <https://registry.iho.int> and <https://ienc.openecdis.org>.

### 1.1.1 Background

Based on the findings of the European transport R&D project INDRIS (Inland Navigation Demonstrator for River Information Services) and the German project ARGO in 2001, both the Danube and the Rhine Commissions adopted an Inland Electronic Chart Display and Information Systems (ECDIS) standard for Electronic Navigational Chart (ENC) data and system requirements for the Rhine and the Danube Rivers. In 2001, the Economic Commission for Europe of the United Nations (UN ECE) adopted the Inland ECDIS Standard as a recommendation for the European inland waterway system (CCNR 2002).

In the USA, following a 1999 recommendation by the National Transportation Safety Board, the U.S. Army Corps of Engineers (USACE) initiated a program to facilitate the production and implementation of Inland ENCs on major river and inland waterway systems in the United States.

While there are some differences between the North American and European inland waterways, there are far more similarities. A North American - European Inland ENC Workshop was held in 2003 in conjunction with a Conference on River Information Services (RIS) organized by the European R&D-project COMPRIS (Consortium Operational Management Platform River Information Services). In addition to informing participants on the status of standards development and projects being conducted, a key objective was to discuss the benefits of harmonizing Inland ENC data standards between Europe and North America.

The North American - European Inland ENC Harmonization Group (IEHG) was formed in 2003 to facilitate the development of international standards for Inland ENC data. The IEHG is comprised of representatives from government, industry and academia. European participants take part on behalf of the European Inland ECDIS Expert Group. The North American participants are members of the North American Inland ENC Ad Hoc working group that was formed in 2002. The IEHG meets once per year. However, most of the work is accomplished via e-mail correspondence, the website <https://ienc.openecdis.org/> and the Inland ENC discussion forum <https://wss.apan.org/army/iehg/>.

The goal of the IEHG is to agree upon specifications for Inland ENCs that are suitable for all known inland ENC data requirements for safe and efficient navigation for European and North American inland waterways. However, it is intended that this standard meets the basic needs for Inland ENC applications, worldwide. As such, the Inland ENC standard is flexible enough to accommodate additional inland waterway requirements in other regions of the world.

In September 2005, the Ministry of Transport of the Russian Federation became a member of the IEHG. In 2007, Brazil through its national Hydrographic Service, the Directorate of Hydrography and Navigation (DHN), joined the IEHG as the first South American country. In October 2009, the Waterborne Transportation Institute of the Ministry of Transport, Peoples Republic of China became the first member of the IEHG from the Asian region.

IEHG also works closely with the International Hydrographic Organization (IHO). At the ECDIS stakeholders' forum in 2007, IHO confirmed that compatibility with Inland ENC standards is allowed by the standards that are certified for maritime ECDIS applications. On 14 April 2009, IEHG became recognized as a Non-Governmental International Organization (NGIO) of IHO. In addition, at the 4th

Extraordinary International Hydrographic Conference on 4 June 2009, IHO adopted a resolution to cooperate with the IEHG.

As an NGIO, IEHG supports, advises and provides input to IHO regarding Inland ENC matters.

## 1.2 S-401 Annex A; Data Classification and Encoding Guide - Metadata

Note: This information uniquely identifies this Annex to the Product Specification and provides information about its creation and maintenance.

## 1.4 Use of language

Within this document:

“Must” indicates a mandatory requirement;

“Should” indicates an optional requirement, that is the recommended process to be followed, but is not mandatory;

“May” means “allowed to” or “could possibly”, and is not mandatory.

## 1.5 Maintenance

Changes to the Data Classification and Encoding Guide must occur in accordance with the S-401 Inland ENC Product Specification clause 1.6.

# 2 General

The S-401 Data Classification and Encoding Guide describes how data describing the real world should be captured using the types defined in the S-401 Feature Catalogue (see S-401 Product Specification Main document clause 4.3). It provides the encoding rules and guidance required to create S-401 ENCs. This standard is specifically concerned with those entities in the real world that are of relevance to hydrography. This hydrographic regime is considered to be geo-spatial. As a result, the model defines real-world entities as a combination of descriptive and spatial characteristics. Within the model these sets of characteristics are defined in terms of feature, spatial and information types. A type is defined as a stereotype of class that is used to specify a domain of instances (features) together with the operations applicable to the features. A type may have attributes and may be related to other types.

The types used within S-401 are described below. Within this document feature types, information types, associations and attributes appear in **bold text**.

## 2.1 Feature types

Feature types contain descriptive attributes and do not contain any geometry (that is, information about the shape and position of a real-world entity).

Features have two aspects – feature type and feature instance. A feature type is a class and is defined in a Feature Catalogue. A feature instance is a single occurrence of the feature type and represented as an object in a dataset. A feature instance is located by a relationship to one or more spatial instances. A feature instance may exist without referencing a spatial instance.

S-401 makes use of the following feature types:

**Geographic (Geo) feature type** – carries the descriptive characteristics of a real-world entity.

**Cartographic feature type** – contains information about the cartographic representation (including text) of real-world entities.

**Meta feature type** – contains information about other features. Information defined by Meta features override the default metadata values defined by the dataset descriptive records. Meta attribution on individual geographic feature instances overrides attribution on Meta features.

### 2.1.1 Multiple features

On some sources, multiple features in close proximity are generalised to a single feature with a text string indicating the presence of the other features. In such cases, where it is considered that this

information may be useful for visual navigation, one feature of the appropriate class should be encoded and the true number of features, if known, must be encoded using the complex attribute **multiplicity of features**, sub-attribute **number of features**, with Boolean sub-attribute **multiplicity known** set to *True* (see clause 27.182). If the true number of features is not known, **multiplicity of features** Boolean sub-attribute **multiplicity known** must be populated as *False*. If **multiplicity of features** is not an allowable attribute for the feature, multiplicity may be indicated using the complex attribute **information**, sub-attribute **text** (for example *3 trees*). If the true number of features is not known, the text *"more than one"* should be encoded using **information (text)**.

Multiple submerged features in close proximity, which have been generalised to a single feature, should not have the multiplicity indicated unless the multiplicity has some significance to safe navigation. This is so as to minimise the presence of Inland ECDIS or ECS "information" symbols, which may contribute to screen clutter (see clause 2.4.6).

For the encoding of multiple, identical lights using the complex attribute **multiplicity of features**, see Table 19-2 in clause 19.1.7.

For the encoding of leading lights that are required to be merged due to scale, see clause 19.1.5.

There is no method within IENC to indicate to the boatmaster that a feature has not been encoded in its true position, therefore it is considered important for features to be encoded in their true position to provide the boatmaster with an accurate representation of the real world.

Encoders are advised, therefore, that if it is required to encode a feature which has been displaced on the source, it should be captured in its real-world position on the IENC.

## 2.2 Information types

An information type is an identifiable object that can be associated with features in order to carry information particular to the associated features. An example of the use of an information type may be the requirement to include a note about overhead cables. Information types can also be associated with other information types. This may be done where there is further supplementary information that is relevant to the information type.

Information types carry attributes but not geometry.

In IENCs information types are used to code navigationally significant information about the feature that cannot be coded by attributes.

## 2.3 Geometric primitives

The allowable geometric primitive for each feature type is defined in the Feature Catalogue. Within this document, allowable primitives are included in the tables containing a description of each feature type. Allowable geometric primitives are point, pointset, curve and surface.

Each spatial value must be referenced by at least one feature instance.

Within this document, allowable primitives are included in the description of each feature type. A feature that may have no geometric primitive is annotated as no geometry (N).

### 2.3.1 Capture density guideline

It is recommended that curves and surface boundaries should not be encoded at a point density greater than 0.3 mm at the optimum display scale for the IENC data.

A curve consists of one or more curve segments. Each curve segment is defined as a loxodromic line on WGS84. Long lines may need to have additional coordinates inserted to cater for the effects of projection change.

The presentation of line styles may be affected by curve length. Therefore, the encoder must be aware that splitting a curve into numerous small curves may result in poor symbolization.

## 2.4 Attributes

Attributes may be simple type or complex type, and are described in Sections 27-30. Complex (C) attributes (Section 29) are aggregates of other attributes that can be simple type (Sections 27 and 28) or complex type. Simple attributes in S-401 are assigned to one of 9 types (see clause 2.4.2).

The binding of attributes to feature types; the binding of attributes to attributes to construct complex attributes; and attribute multiplicity is defined in the Feature Catalogue. Within this document, the allowable attributes are included in the description of each feature type, as well as attribute multiplicity and the allowable values for enumeration type attributes. Where relevant, constraints for other attribute types such as value range for integer and real type attributes; and string format and maximum string length for text type attributes as defined in the Feature Catalogue are also described.

### 2.4.1 Multiplicity

In order to control the number of allowed attribute values; or sub-attribute instances within a complex, S-100 uses the concept of multiplicity. This defines lower and upper limits for the number of values, whether the order of the instances has meaning and if an attribute is mandatory or not. Common examples are shown in Table 2-2 below:

Format : *MinOccurs*, *MaxOccurs* (if \* Infinite) (*ordered*) – sequential

| Multiplicity  | Explanation                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------|
| 0,1           | An instance is not mandatory; there can be only one instance.                                                         |
| 1,1           | An instance is mandatory and there must only be one instance.                                                         |
| 0,*           | An instance is not mandatory and there can be an infinite number of instances.                                        |
| 1,*           | An instance is mandatory and there can be an infinite number of instances.                                            |
| 1,* (ordered) | An instance is mandatory and there can be an infinite number of instances, the order of which has a specific meaning. |
| 2,2           | Two instances are mandatory and no more than two.                                                                     |

**Table 2-2 - Multiplicity - Examples**

Note: The function of the S-57 based attribute type “List” has been replaced by Enumeration (EN) with an upper limit of multiplicity greater than 1. This means that when more than one value is needed for an enumeration type attribute, the attribute code is populated multiple times with the required values.

Example: A red and white tower is encoded with attribute **colour** = 3 (red) and **colour** = 1 (white). Within this document, this example would be indicated as “**colour** = 3,1”.

### 2.4.2 Simple attribute types

Each simple attribute in S-401 is assigned to one of 9 types:

- EN Enumeration: A fixed list of valid identifiers of named literal values. Attributes of an enumeration type may only take values from this list. The complete list of allowable values for S-401 enumeration type attributes is included in Sections 27, 28 and 30; these values may be further constrained for the binding of the attribute to specific feature and information types.
- BO Boolean: A value representing binary logic. The value can be either (1) *True*, (0) *False* or empty (Unknown). The “default state” for Boolean type attributes, unless stated otherwise in this document, is *False* for instances where the attribute is allowable for a feature, is non-mandatory and has not been populated (and is therefore not included for the feature instance). An empty (Unknown) value should only be populated where the Boolean type attribute is mandatory but the value (True or False) is not known to the encoder.
- RE Real: A signed Real (floating point) number consisting of a mantissa and an exponent. The representation of a real is encapsulation and usage dependent.

In S-100, “precision”, as it applies to the IHO GI Registry and the S-401 Feature Catalogue, is defined as a non-negative integer expressing the constraint of the exponent of a real number (that is, “1” means the real number is constrained to a precision of 0.1; “2” means the real number is constrained to a precision of 0.01; etc) (S-100 Part 2a, clause 2a-4.2.10). For the attribute descriptions included in Sections 27, 28 and 30 of this document, the values quoted for precision are expressed in more “human-readable” terms as the exponent of the real type attribute (0.1, 0.01, 0.001, ...).

Examples: 23.501, -0.0001234, -23.0, 3.141296

The maximum number of decimals of numeric attributes is defined in the Feature Catalogue (e.g. XX.dd for maximum two decimals). The encoding of numeric attributes (e.g. of depth information and heights of structures) should reflect the accuracy of the number. For example a bridge height of thirty-five meters, accurate to one meter, has to be encoded as 35, not as 35.0 or 35.00. Measured values without safety margins should be used.

**IN** Integer: A signed integer number. The representation of an integer is encapsulation and usage dependent.

Examples: 29, -65547

**TE** Text: A CharacterString, that is an arbitrary-length sequence of characters including accents and special characters from a repertoire of one of the adopted character sets.

**TD** Truncated Date (S100\_TruncatedDate): Allows a partial date to be encoded as an extension to the ISO 8601 compliant date attribute type values for year, month and day according to the Gregorian Calendar. Character encoding of a date is a string which follows the calendar date format (complete representation, basic format) for date specified by ISO 8601. See clause 2.4.8.

Example: 19610922 (YYYYMMDD)

**TI** Time: A time is given by an hour, minute and second in the 24-hour clock system. Character encoding of a time shall be a complete representation of the basic format as defined in ISO 8601. Complete representation means that hours, minutes and seconds shall be used. Basic format means that separating characters are omitted.

Time may be expressed as Universal Time Coordinated (UTC).

Example: 183059Z

Time is preferably expressed as a Local Time with a given offset to UTC.

Example: 183059+0100

Time may be expressed as a Local Time without a specified offset to UTC.

Example: 183059

The complete representation of the time of 27 minutes and 46 seconds past 15 hours locally in Geneva (in winter one hour ahead of UTC), and in New York (in winter five hours behind UTC), together with the indication of the difference between the time scale of local time and UTC, are used below as examples.

Geneva: 152746+0100

New York: 152746-0500

The service hours for a service, that is available all year in an area where Daylight Saving Hour affects the offset to UTC, could be expressed as Local Time without specified offset.

Example: Opening: 074500 Closing: 161500

**URI** Universal Resource Identifier: A derivation of CharacterString. URI is a uniform resource identifier as defined in RFC 3986. Character encoding of a URI must follow the syntax rules defined in RFC 3986.

For S-401, the attribute type URI is constrained to conformance with the HTTP or HTTPS protocols; that is, the character string must commence with *http://* or *https://*.

Example: *https://registry.iho.int*

**URN** Universal Resource Name: A derivation of the CharacterString predefined derived type Universal Resource Identifier (URI). URN allows a persistent, location-independent, resource identifier to be encoded that follows the syntax and semantics for URNs specified in RFC 2141.

For S-401, the attribute type URN is used mainly to define Maritime Resource Names (MRN), typically in the IEHG namespace – *urn:mrn:iehg:... .*

Example: urn:mrn:iehg:uuid:123e4567-e89b-12d3-a456-426614174000

Real or integer attribute values must not be padded by non-significant zeroes. For example, for a signal period of 2.5 seconds, the value populated for the attribute **signal period** must be 2.5 and not 02.50.

NOTE: For real values between -1.0 and 1.0, the mantissa component zero is considered to be significant. For example, 0.01; -0.999.

### 2.4.3 Mandatory and conditional attributes

Some attributes are mandatory and must be populated for a given feature type. The following are reasons why attribute values may be considered mandatory:

- They are required to support correct portrayal by determining
  - whether a feature is in the display base
  - which symbol is to be displayed;
- Certain features make no logical sense without specific attributes; and
- Some attributes are required for safety of navigation.

In Table 2-3 below, mandatory attributes for which this is relevant for a feature (that is, the attribute should not be populated with an empty (null) value) are indicated by the superscript \*

Within this document, mandatory attributes (multiplicity 1,1; 1,n (n>1); or 1,\*) are identified in the description of each feature type.

NOTE 1: Sub-attributes of complex attributes, as well as the complex attribute itself, may also be designated as mandatory (see NOTE 2 below). "Conditional" mandatory attributes are identified in the feature Tables in Sections 3-24 by the superscript †, with qualifying comments included after the attribute list for the relevant feature.

Compilers must consider these conditional circumstances when encoding features for IENC, as well as any additional information given in the feature class descriptions in this document. For example, when encoding a **Caution Area**, the mandatory attributes are *at least one of* **information** or **pictorial representation** – if the relevant information is textual, **information** must be populated and there is no requirement to populate **pictorial representation**, which therefore should not be populated with an empty (null) value, as it is not mandatory in this case.

NOTE 2: For complex attributes, at least one sub-attribute is mandatory (or conditionally mandatory). Where the sub-attribute of a complex is conditionally mandatory (for example, for the feature **Seabed Area** *at least one of* the sub-attributes **nature of surface** or **nature of surface – qualifying terms** must be populated for the complex attribute **surface characteristics**), this is indicated by the superscript † as for the "Conditional" mandatory attributes described in Note 1 above.

NOTE 3: The attribute **colour pattern** is mandatory for any feature (except lights features) that has more than one value populated for the attribute **colour**.

NOTE 4: The Inland ECDIS or ECS "system" attribute **default clearance depth** must be populated with a value, which must not be an empty (null) value, if the attribute **value of sounding** is populated with an empty (null) value (see clause 30.1).

Optional attributes should be encoded if the value is known.

### 2.4.4 Missing attribute values

Where a value of a mandatory attribute is not known, the attribute must be populated with an empty (null) value (however, see first paragraph of clause 2.4.3 above).

Where the value of a non-mandatory attribute is not known, the attribute should not be included in the dataset.

In a base dataset, when an attribute code is present but the attribute value is missing, it means that the Producer wishes to indicate that this attribute value is unknown.

In an Update dataset, when an attribute code is present but the attribute value is missing it means:

- that the value of this attribute is to be replaced by an empty (null) value if it was present in the original dataset, or
- that an empty (null) value is to be inserted if the attribute was not present in the original dataset.

### 2.4.5 Portrayal feature attributes

The primary use of IENC is within Inland ECDIS or ECS where IENC data is displayed based on the rules defined within the S-401 Portrayal Catalogue. While most Inland ECDIS or ECS portrayal is based on attributes describing the instance of a particular feature in the real world, certain feature attributes are used in portrayal rules to provide additional functionality in the Inland ECDIS or ECS or information to the boatmaster. The following attributes have specific influence on portrayal:

**drawing index** – population of this attribute may assist with the identification of a set of S-401 datasets that are intended to form a seamless presentation, regardless of scale; and identify a hierarchy of such seamless presentations (see clause 3.5 and S-401 Main document clauses 4.6 and 4.7).

**fixed date range; periodic date range** – population of these complex attributes determines when the feature will be added (sub-attribute **date start**) and/or removed (sub-attribute **date end**) from the display in some Inland ECDIS or ECS display settings (see clause 2.4.8).

**information** – population of this complex attribute will result in the display of the magenta information symbol to highlight additional information to the user.

**name usage** – this sub-attribute determines the priority and level of display (full display or Pick Report only) where multiple instances of the complex attribute **feature name** are encoded for a single feature instance, based on boatmaster's selected Inland ECDIS or ECS display settings (see clause 2.5.8).

**pictorial representation** – population of this attribute will result in the display of the magenta information symbol to highlight additional information to the user.

**scale minimum** – value at which the feature will be removed from the display if application of scale minimum is enabled in the Inland ECDIS or ECS (see clause 2.5.9).

**sector line length** – population of this attribute will result in the sector lines and arc radius of the sector being extended by the defined length when the Inland ECDIS or ECS display is set to display default light sectors. See clause 19.3.1.

**visual prominence** – this attribute determines that visually conspicuous features are shown in black colour rather than brown.

#### 2.4.5.1 ECDIS “system” (portrayal) attributes

Attributes designated as “ECDIS system” attributes are intended to provide information specific to aiding in portrayal of features in Inland ECDIS or ECS in certain circumstances; and should be automatically populated by the IENC production software as required. The population of these attributes are conditional dependant on individual encoding instances including the relationship between an encoded feature and the underlying Skin of the Earth feature(s); and resolution of conflicts in portrayal specific to collocated light features. These attributes are described in Section 30 of this document, and include:

**default clearance depth** (see clause 30.1) – this attribute is intended to provide a depth value to the Inland ECDIS or ECS to aid in the display of underwater hazards (**Obstruction, Underwater/Awash Rock, Wreck**) where the actual depth of the underwater hazard is unknown (attribute **value of sounding** populated with an empty (null) value. This value is algorithmically calculated by the production system as required, based on the underlying depth(s) as described in clause 30.1. For S-401 IENCs, **default clearance depth** must be populated with a value, which must not be an empty (null) value, if the attribute **value of sounding** is populated with an empty (null) value.

**in the water** (see clause 30.2) – this Boolean attribute provides an indication to the Inland ECDIS or ECS that features that are located in or over navigable water are to be included in the Inland ECDIS or ECS Base Display. This attribute is automatically populated by the IENC production software where a structure is located over an area of bathymetry (**Depth Area, Dredged Area, Unsurveyed Area**).

**sector arc extension** (see clause 30.3) – this Boolean attribute provides an indication that a distance beyond the default distance at which a light sector arc will be displayed is required where more than one sector light having overlapping sectors has been encoded. This attribute is automatically calculated

and populated as required by the IENC production software. Note that **sector arc extension** is not utilised where light sectors are displayed at the nominal range of the sectors.

**surrounding depth** (see clause 30.4) – this attribute defines a depth value for the area surrounding an underwater hazard to aid in the portrayal of isolated dangers in Inland ECDIS or ECS, and is based on the **depth range minimum value** for the surrounding **Depth Area(s)**. This attribute is automatically calculated and populated as required by the IENC production software. For an area feature covered by more than one **Depth Area**, the value of **surrounding depth** is determined as the depth range minimum value of the deeper of the **Depth Area** features covering the underwater hazard. For S-401 IENCs, **surrounding depth** must be populated with a value, which must not be an empty (null) value.

#### 2.4.6 Textual information

The complex attribute **information** (see clause 29.10) contains information as text using the sub-attribute **text**, or the name of an IENC support file using the sub-attribute **file reference**, in English and, optionally, using multiple instances of **information** to encode the information in one or more additional languages; and where bound to the geo feature classes may be used to encode additional textual information specific to a single feature instance. General conventions for the population of **information** for a feature instance are as follows:

- Where required, only a single mandatory instance of **information** in English (mandatory sub-attribute **language** = *eng* or empty (null)) must be encoded.
- Further optional instances of **information** may also be encoded (sub-attribute **language** populated with the three-letter language code in conformance with ISO 639-2/T) in one or more languages.

The information type **Nautical Information** (see clause 24.4) should be used to encode additional textual information associated to a group of features; and if the information is specific to a single feature, the information should be encoded on the feature itself. The **Nautical Information** is associated to the relevant features using the association **Additional Information** (see clause 25.1).

The complex attribute **information** must not be used when it is possible to encode the information by means of any other attribute. Under certain Inland ECDIS or ECS display settings the “information” symbol will display when this attribute is populated. Therefore Producers should carefully consider use of this attribute as the symbol may contribute significantly to Inland ECDIS or ECS screen clutter.

Character strings contained in **information** sub-attribute **text** must be UTF-8 character encoding. **Information** should generally be used for short notes or to transfer information which cannot be encoded by other attributes, or to give more detailed information about a feature. Text populated in **text** must not exceed 300 characters.

The exchange language for textual information should be English. Languages other than English may be used as a supplementary option, for which **language** must be populated with an appropriate value to indicate the language. Generally this means, when a national language is used in the textual attributes, the English translation must also exist.

##### Remarks:

- For Guidance on encoding names of features, see clause 2.5.8.

#### 2.4.7 Spatial attribute types

Spatial attribute types must contain referenced geometry and may be associated with spatial quality attributes. Each spatial attribute instance must be referenced by a feature instance or another spatial attribute instance.

**Figure 2-1 – Spatial Quality information type**

Spatial quality attributes are carried in the information type **Spatial Quality** (see clause 24.5). Only point, multipoint and curve geometry and the Meta feature **Quality of Bathymetric Data** can be associated with **Spatial Quality**. Currently no use case for associating surfaces with spatial quality attributes is known, therefore this is prohibited; however it is allowable for **Spatial Quality** to be associated with the curves comprising the spatial edges (boundaries) of surface features. Vertical uncertainty is prohibited for curves as this dimension is not supported by curves.

## 2.4.8 Dates

When encoding dates using the attributes **dredged date**, **fixed date range**, **reported date**, **reference year for magnetic variation**, **survey date range** and **swept date**, the following values must apply in conformance to S-100.

- Full date: YYYYMMDD
- No specific day required: YYYYMM--
- No specific month required: YYYY----

If it is required to encode periodic/recurring dates using the attributes **date fixed** and **periodic date range**, the following values must apply in conformance to S-100.

- No specific year required, same day each year: ----MMDD
- No specific year required, same month each year: ----MM--

Notes: YYYY = calendar year; MM = month; DD = day.

The dashes (-) indicating that the year, month or day is not needed must be included.

Encoded date ranges are inclusive, see S-100 Part 3, clause 3-8.3. For example:

**fixed date range/date start** = 20220922 Commences at 000000 hours on 22 September 2022  
**fixed date range/date end** = 20221022 Ends at 240000 hours on 22 October 2022.

**periodic date range/period start** = ----09-- Commences annually at 000000 hours on 01 September.

**periodic date range/date end** = ----09-- Ends annually at 240000 hours on 30 September.

Where the temporal attributes have been encoded for any feature that is the structure component of a **Structure/Equipment** feature association (see clause 25.12), all other component features within the relationship must not extend beyond the temporal attribute values encoded for the structure feature.

### Reported date (SORDAT)

US: **Reported date** (SORDAT) is a mandatory attribute and must be coded for all features in the IENC. **Reported date** (SORDAT) should be set to the release date of the chart if the actual source dates of the data unavailable.

EUR: **Reported date** (SORDAT) for other features it might be set to "unknown".

BR: **Reported date** (SORDAT) is optional.

#### 2.4.8.1 Seasonal features

If it is required to show seasonality of features, it must be done using the attribute **status** = 5 (periodic/intermittent). If it is required to encode the start and/or end dates of the season, this must be done using the complex attribute **periodic date range** (see clauses 2.4.8 and 29.16).

Where there is a requirement to indicate the beginning or end date of a seasonal occurrence as the "last day in February", consideration must be given to allowing for the extra day (29<sup>th</sup> February) added on leap years. Encoding **periodic date range**, sub-attribute **date end** with the value ----0228 may result in erroneous indication of seasonality in the Inland ECDIS or ECS on the 29<sup>th</sup> February for leap years, while encoding the value ----0229 may similarly result in Inland ECDIS or ECS performance issues for non-leap years. Encoders are advised, therefore, that where it is required to encode the end of seasonality as the last day in February, this must be done, similar to any other month of the year, by encoding the value of **periodic date range**, sub-attribute **date end** as ----02--. Where the beginning of seasonality is the last day in February, this must be done by encoding the value of **periodic date range**, sub-attribute **date start** in accordance with the next occurrence of the date (----0228 if the next occurrence is a non-leap year or ----0229 if the next occurrence is a leap year). The IENC dataset must be amended by IENC Update (see Section 31) where the date is required to be changed. For instance, if the value is ----0228 and the next occurrence is a leap year, an IENC Update must be created to amend the date to ----0229.

Alternatively, if encoders consider that there is no regulatory requirement to update the start date of a period for leap years, the value of **date start** may be populated as ----03--, indicating a beginning date of 01 March each year.

#### 2.4.9 Times

If it is required to show the beginning and end of the active time period of a feature, it must be encoded using the attributes **time of day end** (see clause 27.248) and **time of day start** (see clause 27.249). The attribute descriptions for **time of day end** and **time of day start** state that the format must conform to ISO 8601, and this format must be used (see also clause 2.4.2).

Time may be expressed as Universal Time Coordinated (UTC). Where required, this must be done using the format *hhmmssZ*, with 2 digits for the hour (*hh*), 2 digits for the minutes (*mm*) and 2 digits for the seconds (*ss*); and “Z” mandatory.

EXAMPLE: *183059Z* to represent a UTC time of 30 minutes and 59 seconds after 6 o'clock in the evening

Time is preferably expressed in Local Time with a given offset to UTC. This must be done using the format *hhmmss+hhmm*.

EXAMPLE: *183059+0100* to represent a local time that is 1 hour ahead of UTC

In areas that are subject to daylight saving hours during certain periods of the year, it may be more appropriate to provide local times that are independent of a UTC offset. If it is required to express Local Time without a specified offset to UTC, this must be done using the format *hhmmss*.

EXAMPLE: *183059* to represent a local time of 30 minutes and 59 seconds after 6 o'clock in the evening

### 2.4.9.1 Schedules

If it is required to indicate the time schedule associated with any feature, it can be encoded using the information types **Service Hours** (see clause 24.2) or **Non-Standard Working Day** (see clause 24.3) especially if the information should be available for maritime vessels. **Service Hours** is used to indicate the regular operational schedule and/or times of closure for a service related to a feature. **Non-Standard Working Day** is used to indicate specific days of the year when normal working hours are limited, and may not be related to the Gregorian calendar.

EXAMPLE: A feature service is available under normal operation status 24 hours/day on Monday and Wednesday and from 08:00 to 16:00 (local time – note the format for local time with specified offset to UTC in clause 2.4.9 above) from Thursday to Saturday. The service is not available on public holidays and the 05 of August of each year.

#### Service Hours

**schedule by day of week**

**category of schedule** = 1 (normal operation)

**time intervals by day of week**

**day of week** = 2,4 (Monday, Wednesday)

**day of week is range** = 0 (false – indicates that **day of week** includes Monday and Wednesday only)

**time intervals by day of week**

**day of week** = 5,7 (Thursday, Saturday)

**day of week is range** = 1 (true – indicates that **day of week** includes the range of days Thursday, Friday and Saturday)

**time of day start** = *080000+0100*

**time of day end** = *160000+0100*

#### Non-Standard Working Day

**date fixed** = - - - -0805 (05 August each year)

**date variable** = *public holidays*

There can be different **Service Hours** for different **direction of impact**, **type of ship** or **use of ship** values.

### 2.4.10 Colours and colour patterns

If it is required to encode multiple colours on a feature, they must be encoded using the attributes **colour pattern** and **colour** as follows:

- For horizontal stripes (**colour pattern** = 1), the values for **colour** must be ordered such that the first colour is the top-most, and subsequent colours follow sequentially from top to bottom. For example, **colour** = 3,1 to encode a red stripe above a white stripe.
- For vertical stripes (**colour pattern** = 2), the values for **colour** must be ordered such that the first colour is the left-most, and subsequent colours follow sequentially from left to right. For example, **colour** = 3,1,3 to encode red, white, red vertical stripes

- For diagonal stripes (**colour pattern** = 3), the values for **colour** must be ordered such that the first colour is the top-left-most, and subsequent colours follow sequentially from top left to bottom right. For example, **colour** = 1,3,1,3,1 to encode white, red, white, red, white diagonal stripes.
- For squares (**colour pattern** = 4), the values for **colour** must be ordered such that the first colour is the top-left-most square. Subsequent colours follow sequentially from left to right along the top row then repeated for subsequent rows until the bottom right-most square is reached. For example, **colour** = 1,3,3,1 to encode white, red squares on the top row and red, white squares on the bottom row.
- For border stripes (**colour pattern** = 6), the values for **colour** must be ordered such that the first colour is the border stripe, and the second colour that of the background. For example, **colour** = 3,1 to encode a red border stripe on a white background. Where a border stripe is combined with other patterns, an assessment as to which pattern is most important to marine navigation must be made, and the appropriate value populated in **colour pattern**.

Note that the attribute **colour pattern** is mandatory for any feature (except lights) that has more than one colour.

If the encoded colours and colour pattern for feature is considered to be complex, it is strongly recommended that an image of the feature, if available, is also included using the attribute **pictorial representation**.

#### 2.4.11 Radar conspicuous features

The Boolean attribute **radar conspicuous** is used to encode whether or not a feature is radar conspicuous.

##### Remarks:

- If it is required to encode a feature which has no radar reflector, but is radar conspicuous, it must be indicated using attribute **radar conspicuous** = *True*.
- If it is required to encode a surface or point feature which is radar conspicuous because it is fitted with a radar reflector, it must be indicated using attribute **radar conspicuous** = *True* on the feature where **radar conspicuous** is an allowable attribute. Where **radar conspicuous** is not an allowable attribute for the feature, a **Radar Reflector** feature (see clause 20.15) must be encoded within or coincident with the feature.
- If it is required to encode radar reflectors on curve features (for example overhead cables), this must be done using the feature **Radar Reflector**.

#### 2.4.12 Attributes referencing IENC support files

The complex attribute **information** and its sub-attribute **file reference** on the information type **Nautical Information** (see clause 24.4) or on individual geo features references textual IENC support files. The simple attribute **pictorial representation** on **Nautical Information** or on individual geo features references picture files. The association **Additional Information** (see clause 25.1) is used to create an association between the geo feature(s) and **Nautical Information** where required. Where the information is relevant to a single feature instance only, it should be encoded using **information** or **pictorial representation** on the feature instance. Where the information is relevant to multiple feature instances, it should be encoded using **information** or **pictorial representation** on an associated instance of **Nautical Information**. See also clause 2.4.6.

The attributes **information** and **pictorial representation** are considered portrayal feature attributes (see clause 2.4.5), meaning that under given circumstances the “information” symbol (magenta “i”) will be portrayed in Inland ECDIS or ECS when one or both of these attributes are populated. Due to risk of Inland ECDIS or ECS screen clutter, Producers should carefully consider the use of these attributes.

These attributes must not be used when it is possible to encode the information by means of any other attribute.

Clause 11.2 of the S-401 Product Specification Main document specifies the content of an Exchange Set and the inclusion of support files. Clause 11.4 of the Product Specification Main document outlines specific rules and limitations for support files and their management; and additionally details IENC support file creation and application use cases

#### 2.4.12.1 Reference to textual IENC support files

The IENC support files referenced by the complex attribute **information**, sub-attribute **file reference**, must be .TXT files, and may contain formatted text. These files should generally be used for longer texts (for example longer chart notes, tables or paragraphs from Nautical Publications), but should not be used to replicate large blocks of text (for example entire chapters of Sailing Directions) that can be found in other Nautical Publications, which may not be suitable for viewing in Inland ECDIS or ECS. It is up to the Producing Authority to determine the most suitable means of encoding a particular piece of text. Textual IENC support files must be encoded using the character set defined in ISO 10646-1, in Unicode Transformation Format-8 (UTF-8).

The exchange language for textual information should be English. The sub-attribute **language** must be populated with an appropriate value to indicate the language used. Languages other than English may be used as a supplementary option. Generally this means, when a national language is used in the textual attributes, the English translation must also exist.

##### Remarks:

- Encoders must encode national language IENC support files (files referenced by the sub-attribute **file reference**) using UTF-8 character encoding. This means that the encoding of the characters in these files must match the encoding of other textual national attributes (that is, **feature name**, **information (text)** with value other than English populated for sub-attribute **language**) within the dataset.
- Note that filename must be in UPPER CASE.  
 US: Format is AARRMMXNN.EXT where:  
 AA = 2-character Producer Code  
 RR = 2-character river code  
 MMM = 3-digit river mile or river km, 000-999  
 X = tenth of river mile/km; preceding decimal point implied; use zero if river mile/km known only to the nearest mile.  
 NN = 01-99; unique identifier for text file at the particular river mile/km.  
 For example, if three TXTDSC files exist at the same river mile/km, 01, 02, and 03 would be used.  
 EXT = 3-character file extension for Hypertext Metafile (HTM), ASCII text (TXT), or Standardized External XML file with communication information.

EUR: The ISRS Location Code or the UUID (which can be part of the Maritime Resource Name (MRN)) can be used for the file name, e.g. DEXXX039000000005023.XML or 123e4567-e89b-12d3-a456-426614174000.XML.

#### 2.4.12.2 Reference to pictorial IENC support files

The attribute **pictorial representation** should only be populated where the information is considered important in terms of safety of navigation and protection of the marine environment. Pictorial IENC support files that form part of the IENC must be in Tagged Image File (TIF) format 6.0 or JPG.

Encoders should also consider, when including a reference to a pictorial IENC support file, whether the file is appropriate in terms of:

- Size of the file: Pictorial files should be kept to a minimum file size, and should be considered in relation to the maximum allowable size of an IENC dataset (10Mb). Therefore, for example, a pictorial file of 100Mb should be considered to be inappropriate. Using the following values as a guideline for TIF files will ensure acceptable size pictorial IENC support files:

|                         |                |
|-------------------------|----------------|
| Recommended Resolution: | 96 DPI         |
| Minimum Size x,y:       | 200,200 pixels |

|                   |                      |
|-------------------|----------------------|
| Maximum Size x,y: | 800,800 pixels       |
| Bit Depth:        | 8 Bit Indexed Colour |
| Compression:      | LZW                  |
| Format:           | Tiff 6.0             |

**Table 2-4 – Recommended formatting for TIF files used as IENC support files**

- Content of the graphic: The information contained in the pictorial file should supplement, in terms of navigational relevance, the encoding of the associated feature. For example, an image of a standard IALA special purpose buoy that duplicates the attribution of the associated **Special Purpose/General Buoy** provides no relevant supplementary information to the boatmaster (and may be considered to be double encoding), and therefore should not be included.
- Aspect: Graphics should provide perspective relevant to the view of the boatmaster. For example, an image of the top of a bridge derived from a photograph taken from the top of a bridge tower or nearby building does not provide the boatmaster with any information relevant to their location, and should not be included. However, an image derived from a photograph taken from a vessel approaching the bridge may be considered relevant.
- Suitability for display in Inland ECDIS or ECS: Graphics should be such that all the information in the pictorial file is legible in the Inland ECDIS or ECS display. For example, text included in diagrams or tables must be large enough so as to be legible when the file is opened in the Inland ECDIS or ECS display. Images included in a pictorial file should also be appropriately scaled such that they comfortably fit in the picture display window on the Inland ECDIS or ECS (that is, do not only take up a very small area of the window; or are so large that the image needs to be panned to see the entire image). Consideration must also be given to variation in ships' bridge lighting conditions. It is recommended that, where possible, ENC support files are tested by opening the file in an Inland ECDIS or ECS prior to publication of the IENC.
- Note that the filename must be in UPPER CASE.  
 Format is AARRMMXNN.EXT, where:  
 AA = 2-character Producer Code  
 RR = 2-character river code  
 MMM = 3-digit river mile or river km, 000-999  
 X = tenth of river mile/km; preceding decimal point implied; use zero if river mile/km known only to the nearest mile.  
 NN = 01-99; unique identifier for image file at the particular river mile/km.  
 For example, if three PICREP files exist at the same river mile/km, 01, 02, and 03 would be used.  
 EXT = 3-character file extension for the image file format; most commonly TIFF (TIF) or JPEG (JPG) formats.

### 2.4.13 UN Location Code

The attribute **UN location code** (UNLOCD) has been used to encode the UN Location Code (<http://www.unece.org/cefact/locode/service/main.htm>) or, in Europe, the Inland Ship Reporting Standard (ISRS) Location Code; which is used to establish a standardized relation to other River Information Services. It should only be encoded for new features if it is intended to publish Application Specific Messages (ASM) via Inland AIS for those features.

### 2.4.14 Interoperability Identifier

See inland specific encoding instructions in 27.161.

## 2.5 Datasets

A Dataset is a grouping of features, attributes, geometry and metadata which comprises a specific coverage.

Four types of IENC dataset may be produced and contained within an exchange set:

- Update: Changing some information in an existing dataset.
- Re-issue of a dataset: Including all the Updates applied to the original dataset up to the date of the reissue. A Re-issue does not contain any new information additional to that previously issued by Updates.
- New dataset and New Edition of a dataset: Including new information which has not been previously distributed by Updates. Each New Edition of a dataset must have the same name as the dataset that it replaces.

See also S-401 Main document, Section 4.5 in addition to the sub-clauses below for further information regarding IENC datasets.

### 2.5.1 IENC data coverage

An IENC dataset can contain more than one **Data Coverage** (see clause 3.5). The data boundary is defined by the extent of the **Data Coverage** Meta features. Data must only be present within **Data Coverage** Meta features.

Producers must not leave “holes” (that is, areas not covered with data) in smaller scale range coverage, under the assumption that the Inland ECDIS or ECS user will have the larger scale data available. For areas covered by larger scale IENCs, well established cartographic data generalization practices should be applied, including the inclusion of minimum depiction areas (see clause 2.5.3.2 below).

An IENC Update dataset must not change the extent of the data coverage for the base IENC cell. Where the extent of the data coverage for a base IENC cell is to be changed, this must be done by issuing a New Edition of the cell.

#### 2.5.1.1 Skin of the Earth

Each area covered by a Meta feature **Data Coverage** must be totally covered by a set of geo features of geometric primitive type surface that do not overlap each other (the Skin of the Earth). Feature types that comprise the Skin of the Earth are listed below:

**Depth Area**

**Dredged Area**

**Land Area**

**Unsurveyed Area**

The geometry of coincident boundaries between Skin of the Earth features in a dataset must not be duplicated.

### 2.5.2 Discovery metadata

Information regarding discovery metadata can be found in the S-401 Inland ENC Product Specification (main document).

### 2.5.3 Minimal depiction areas

Where minimal depiction areas exist in a specified IENC optimum display scale, they should be encoded using one of the following options:

#### 2.5.3.1 Wide blank areas

Areas of a dataset which contain no data must be excluded from the area(s) covered by the Meta feature **Data Coverage**. The areas that contain data must be completely covered by **Data Coverage** features.

### 2.5.3.2 Simplified or minimum depiction areas

- Bathymetry in such areas should be encoded as described in clause 11.7.2.
- Information that does not relate to bathymetry but is relevant to land area features may be encoded.
- One **Caution Area** feature covering the whole area should be created. The complex attributes **information** (sub-attribute **text** or **file reference**) should be encoded using one of the following options (the textual content of the attributes (for **file reference** this will be the contents of the referenced IENC support file) is within quotation marks and italicised):

Where larger scale coverage is available:

*“Most features, including bathymetry, are omitted in this area. The minimal depiction of detail in this area does not support safe navigation; boatmasters should use a more appropriate scale IENC.”*

Any other relevant information pertaining to the area should be incorporated within, or replace completely, the above statement.

Where no larger scale coverage is available:

*“Most features, including bathymetry, are omitted in this area. The minimal depiction of detail in this area does not support safe navigation.”*

This statement should be supplemented by additional cautionary information relating to any authority to be consulted before navigating in the area.

### 2.5.4 Units

The depth, height and positional uncertainty units in a dataset must be metres.

### 2.5.5 Seamless IENC coverage

IENCs should form a seamless coverage in the navigable waters of the Producer's area of responsibility. However, it is often impractical to do so for all Inland ECDIS or ECS display scales, and therefore S-401 IENCs declare a scale range, which dictate between what scales the data can be used.

The Meta feature **Data Coverage** (see clause 3.5) is used to provide the Inland ECDIS or ECS with the scale information necessary for the determination of dataset loading and unloading in relation to the user selected viewing scale in the Inland ECDIS or ECS.

The mandatory attribute **optimum display scale** is used to indicate the intended viewing scale for the data. This may be considered by the Data Producer to be the compilation scale for the data, and is also used as the reference for the overscale indication. The mandatory attribute **minimum display scale** is used to indicate the smallest intended viewing scale for the data. The mandatory attribute **maximum display scale** is used to indicate the value considered by the Data Producer to be the maximum (largest) scale at which the data is to be displayed before it can be considered to be “grossly overscaled”.

An IENC dataset (discovery metadata) and associated **Data Coverage** feature(s) must carry a value for **optimum display scale**. Each **Data Coverage** feature must also carry a value for **maximum display scale** and **minimum display scale**. Values for **optimum display scale** and **minimum display scale** must be taken from the list of values defined in Table 3-2 at clause 3.5.1.

The **Data Coverage** features within a dataset must not overlap, however **Data Coverage** features from different datasets may overlap as long as the **optimum display scale** and **minimum display scale** ranges do not overlap and, if populated, they do not have the same value for the attribute **drawing index**. All **Data Coverage** features within a dataset must have the same value for **minimum display scale** and, if populated, **drawing index**, but portions of a dataset can have a different optimum and maximum display scale, depending on the best scale required for navigation in an area for the purpose of the IENC data.

Datasets that share a common minimum display scale will form a seamless presentation when rendered in the end-user system. When datasets do not share a common minimum display scale but are still intended to form a seamless presentation, this should be indicated by using a common drawing index.

Datasets with a common minimum display scale or drawing index must not contain overlapping data coverage features.

To ensure a seamless Inland ECDIS or ECS display of IENC data within the same scale range, it is important that the data on the border of the dataset is aligned and matched with the corresponding data in any adjoining datasets within the scale range, where possible. Where there is a mismatch in depth data between adjoining datasets, editing of the depth data should be done such that depth contours and depth areas are adjusted on the side of safety. Edge matching of data across different scale ranges, particularly depth data, is often not possible due to generalisation issues resulting from differing scales, although features such as maritime boundaries, navigation lines, recommended tracks, roads etc. should be edge matched where possible. Note that point or curve features which are at the border of **Data Coverage** features (see clause 3.5) for adjoining datasets with the same scale range must be part of only one dataset.

In areas which include neighbouring Producer Nations, producers should co-operate to agree on dataset boundaries and ensure no data overlap within scale ranges, or disparate drawing indices. Where datasets are intended to provide a seamless presentation at national boundaries and a common minimum display scale cannot be agreed, a common drawing index should be agreed. Where possible, adjoining nations should agree on common data boundaries within a technical arrangement based on cartographic convenience and benefit to the boatmaster. Suitable communications between neighbouring nations should be put in place to ensure data consistency across dataset boundaries. These should include exchange mechanisms to allow access to each other's IENCs.

### 2.5.6 Feature Object Identifiers

Each feature instance within an IENC must have a unique universal Feature Object Identifier [FOID]. Information regarding FOIDs can be found in clause 4.4 of the S-401 Inland ENC Product Specification (main document).

### 2.5.7 Heights and elevations

**Figure 2-2 – Heights and elevations**

If it is required to encode the altitude of natural features above a vertical datum (for example hills, coastlines, slopes), with the exception of trees, it must be done using the attribute **elevation** (Figure 2-2 (a)).

For artificial features (for example landmarks, buildings) or trees:

- If it is required to encode the altitude of the ground level at the base of the feature, or the elevation of a light, above a vertical datum, it must be done using **elevation** (Figure 2-2 (b)).
- If it is required to encode the altitude of the highest point of the feature above a vertical datum, it must be done using the attribute **height** (Figure 2-2 (c)).

- If it is required to encode the height of the feature above ground level, the seabed or (for floating features) the sea surface (that is, not associated with a vertical datum), it must be done using the attribute **vertical length** (Figure 2-2 (d)).

### 2.5.8 Geographic names

If it is required to encode a geographic name, or multiple versions of a geographic name including multiple language versions of the name, it must be done using one of more instances of the complex attribute **feature name** (see clause 29.3). When possible, existing features (for example **Built-Up Area**, **River**, navigational marks) should be used to carry this information.

If it is required to encode a geographic name for which there is no existing feature, a specific **Administration Area**, **Sea Area/Named Water Area** or **Land Region** feature must be created (see clauses 16.9, 9.1 and 5.8 respectively). In order to minimise the data volume, these features should, where possible, use the geometry of existing features, for example a **Sea Area/Named Water Area** feature may use the geometry of a **Depth Area** feature.

Geographic names can be left in their original language in a non-English iteration of the sub-attribute **name**, or transliterated or transcribed and used in an English iteration of the sub-attribute **name**, in which case the original name should be populated in an additional iteration of **feature name** with the mandatory sub-attribute **language** populated with the relevant three-letter language code in accordance with ISO 639-2/T. Examples of encoding of **feature name** are included in Table 2-5 below. General conventions for the population of **feature name** for an encoded feature instance are as follows:

- Where it is intended that a name of a feature instance is to be displayed in the Inland ECDIS or ECS, one or more iterations of **feature name** must be encoded for the feature, with exactly one of these instances having the sub-attribute **name usage** = 1 (default name display). This should normally be the English version of the name (mandatory attribute **language** = eng), however this is at the discretion of the Data Producer.
- Where only a single instance of **feature name** and having sub-attribute **name usage** = 1 is encoded for a feature instance, this name will be displayed in both the “default” Inland ECDIS or ECS language setting and the “alternate” Inland ECDIS or ECS language setting.
- Multiple instances of **feature name** may be encoded for any language, and/or for multiple languages. Where multiple instances of **feature name** are encoded for a feature instance, they must be encoded as follows in order to ensure the desired Inland ECDIS or ECS display in both the default and alternate Inland ECDIS or ECS language display settings:
  - If the name is intended to be displayed in the “default” Inland ECDIS or ECS display, exactly one of instance of **feature name** having the sub-attribute **name usage** = 1 (default name display) must be included. Where other instances of **feature name** having the same value for the mandatory attribute **language** have been encoded, the attribute **name usage** must not be populated.
  - If an alternate language name is intended to be displayed in the “alternate” Inland ECDIS or ECS language setting, at least one instance of **feature name** having attribute **language** populated with a value other than the “default” language must be encoded, and having the value for the sub-attribute **name usage** = 2 (alternate name display). Only one **feature name** instance having **name usage** = 2 can be encoded for a single language; and for all **feature name** instances having an instance(s) of **name usage** = 2 there must be a feature instance having **name usage** = 1 encoded as the “default” language instance.
  - Where the language(s) selected by the boatmaster as the “alternate” language(s) is different from the alternate language(s) encoded for a feature instance, the “default” name will be displayed at all times.
  - If it is required to restrict the display of all instances of **feature name** encoded for a feature instance only to the Inland ECDIS or ECS Pick Report, **name usage** must not be populated for any instance.
  - All encoded instances of **feature name** will be included in the Inland ECDIS or ECS Pick Report.
- Reasons for encoding more than one instance of **feature name** for a particular language include (but are not limited to):
  - For cartographic reasons, for example to abbreviate a name using an international abbreviation.

- To allow an identifier/designator to be displayed in preference to the name of the feature (for example on aids to navigation).

In the following examples, a dash in the **name usage** sub-attribute column indicates that the sub-attribute must not be populated.

|                                                        |                 |                   |                                                                                   |                                                                                                                                          |                       |
|--------------------------------------------------------|-----------------|-------------------|-----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| <b>S-401 Feature: Sea Area/Named Water Area</b>        |                 |                   |  | <b>Name displayed in Inland ECDIS or ECS<br/>(based on display of names enabled<br/>and boatmaster's selected language<br/>settings)</b> |                       |
| <b>Complex attribute feature name, sub-attributes:</b> |                 |                   |                                                                                   |                                                                                                                                          |                       |
| <b>name</b>                                            | <b>language</b> | <b>name usage</b> |                                                                                   | <b>Language setting</b>                                                                                                                  | <b>Name displayed</b> |

**Table 2-5 – Complex attribute feature name encoding - examples**

Geographic names should be encoded using **feature name** based on the following criteria and at the producers discretion:

1. Named points or capes that do not contain navigational aids should be encoded as **Land Region** features (of type surface or point), with the geographic name encoded using **feature name**.
2. Named points or capes that contain one navigational aid should be encoded using **feature name** on the structure feature associated with the navigational aid. If more than one navigational aid exists on the point or cape or if the point or cape and the structure feature have different names, a **Land**

- Region** feature (of type surface or point) should be encoded, with the geographic name of the point or cape encoded using **feature name**.
3. A group of hydrographic features (for example **Seabed Area**, **Underwater/Awash Rock**, **Obstruction**, **Sounding**), associated with a particular geographic name, should have the name encoded using **feature name** on a **Sea Area/Named Water Area** feature (of type surface or point). The name should not be encoded on the individual hydrographic features.
  4. A major island name close to primary shipping corridors should be encoded using **feature name** on the **Land Area** feature delimiting the island.
  5. n.a.
  6. Named features listed in the communications of the navigation authorities that may assist in navigation should be encoded using **feature name** on the relevant feature (for example **Land Region**, **Underwater/Awash Rock**, **Seabed Area**, **Sea Area/Named Water Area**, **Obstruction**).
  7. If it is required to encode an administrative area of international, national, provincial or municipal jurisdiction that may have legal inference, it must be done using an **Administration Area** feature, with the name encoded using **feature name**.
  8. If it is required to encode a major city along the coast, it must be done using **Built-Up Area** or **Administration Area** features (see clause 6.1), with the name encoded using **feature name**.
  9. If it is required to encode the name of a navigable river, lake or canal, it must be done using a **Sea Area/Named Water Area** feature, with the name encoded using **feature name**.
  10. If it is required to encode the name of a beach and no intertidal area exists, it should be done using **feature name** for the section of sandy coast (**Coastline** with **nature of surface** = 4 (sand)) representing the beach. If the extent of the beach cannot be determined from the source, then the name should be encoded using **Land Region**. When an intertidal area (**Depth Area**) exists in the area covered by the named beach, the name of the beach should be encoded using **feature name** for a **Sea Area** feature covering the intertidal area.

In all instances, if the exact extent of the feature to be named is known, a surface feature must be created. If the exact extent is not known, or the area is too small at the optimum display scale of the IENC dataset, an existing or specifically encoded point feature should be used to encode the geographic name.

Do not include information on characteristics of a feature in the feature name. The name must be in Title Case. Abbreviations should be used where possible. Only short names should be used to avoid clutter in the display.

US: Any important navigation notes that should always be shown on the IENC should be encoded as **Land Region** (LNDRGN) (P) on land or **Sea Area** (SEAARE) (P) features in the water.

EUR: Use the appropriate feature to display information (e.g. **Communication Area** (comare)).

### 2.5.8.1 Text placement

The cartographic feature **Text Placement** (see clause 23.1) is used specifically to place text cartographically. The properties of the text placement feature are described as follows;

**Geometry (point)** – the spatial point location of the text string.

**text type** – the classification of the text being placed based on attribution of the target feature(s) (mandatory).

**text offset bearing** and **text offset distance** – the bearing and distance (in millimetres in the Inland ECDIS or ECS display) used to position the text relative to the feature.

The **Text Placement** feature is associated to the feature which carries the text being placed. The mandatory attribute **text type** identifies the text string(s) to be placed. The **Text Placement** feature may provide functionality such that, as an Inland ECDIS or ECS screen rotates from its optimum position in “head up” display mode (for example, if display is set to “north up”) text can remain readable, or clear other important charted information.

### 2.5.9 Sample scale minimum policy

The values for the scale minimum mentioned for the individual features are recommendations for European and American waterways. The chart producer might deviate from these values in order to improve the chart display in special situations, for example on very small or very large waterways. The value of **scale minimum** (SCAMIN) has to be set to a scale value smaller than or equal to the compilation scale of the data for the area.

For other IENCs the following policy for the application of **scale minimum** (see clause 27.218) to an IENC portfolio which is based on the mandatory **optimum display scale** values listed in clause 3.5.1 has to be taken into account. While the procedure described below to determine the **scale minimum** value for features in an IENC cell is recommended, the **scale minimum** values used are at the discretion of the producer. Producers should cooperate at the regional level to determine a **scale minimum** policy that results in suitable and consistent display of IENC data for the boatmaster across and, where required between, regions.

**scale minimum** values used should be selected from the following list if the values mentioned for the individual features and regions are not used:

| Scale                                                                                                   |
|---------------------------------------------------------------------------------------------------------|
| NULL (only allowed on minimum display scale (data will continue to be displayed at all smaller scales)) |
| 1:10,000,000                                                                                            |
| 1:3,500,000                                                                                             |
| 1:1,500,000                                                                                             |
| 1:700,000                                                                                               |
| 1:350,000                                                                                               |

| 1:8,000                                                                                                 |
| 1:4,000                                                                                                 |
| 1:3,000                                                                                                 |
| 1:2,000                                                                                                 |
| 1:1,000                                                                                                 |
| 1:500                                                                                                   |
| 1:200 (only allowed on optimum and maximum display scale)                                               |

**Table 2-6 – scale minimum values**

- **scale minimum** values for features within an IENC should be set to either 1, 2, 3 or 4 steps smaller scale than the optimum display scale of the IENC data.

Following this process provides an automated approach to setting **scale minimum** which takes account of the relative importance of different feature classes, and will achieve sufficient de-cluttering even where there are large gaps in the scales of coverage available.

This approach takes no direct account of the relative importance of individual occurrences of a feature, and may result in the situation where a feature disappears and then reappears as the user zooms out on their Inland ECDIS or ECS display. To address these remaining issues, the following additional process steps should be applied:

- Linear and area features (excluding those features subject to extensive generalisation for example **Depth Contour**) that extend beyond the coverage of a dataset and exist in an overlapping smaller

scale dataset should be assigned the same **scale minimum** value as the **scale minimum** value of the corresponding feature in the smaller scale dataset.

- The **scale minimum** value of an individual occurrence of a feature should be set to either 1, 2, 3 or 4 steps smaller scale than the optimum display scale of the smallest scale IENC that the feature would appear on (that is, assuming full coverage across all optimum display scale values).
1. It is generally accepted that features making up a navigational aid will have the same attributes, and therefore features within a **Structure/Equipment** association (see clause 25.12) should be assigned the same **scale minimum** value.
  2. The elements comprising a range system (see clause **Fehler! Verweisquelle konnte nicht gefunden werden.**) should have the same **scale minimum** value, which should be the value corresponding to the largest step value of the features comprising the range system. For instance, for a range system comprising a **Navigation Line**, **Recommended Track** and navigation aids, the decision may be not to apply **scale minimum** to the navigation aids, in which case the **Navigation Line** and **Recommended Track** should also not have **scale minimum** applied. Similarly, all features comprising a routeing measure (see clause 10.2) should have the same **scale minimum** value.
  3. Where features having curve or surface geometry extend over multiple **Data Coverage** areas (see clause 3.5), the value for **scale minimum** should be populated based on the largest scale denominator populated for the attribute **optimum display scale** on the underlying **Data Coverage** areas. The same approach should also be considered for items included in feature associations such as range systems and routeing measures, also taking into account Note 2 above.

### 2.5.10 Masking

*Figure 2-5 – Overwriting symbols – Example*

To improve the look and feel of the display of IENCs in Inland ECDIS or ECS for the boatmaster certain edges of features should be masked (see S-401 Product Specification Main document clause 4.8.3). For example, the boundaries of anchorage area symbols overwrite coincident pontoon symbols:

In order to best determine the appropriate level of masking required for an IENC cell, it is recommended that the IENC be viewed in an Inland ECDIS or ECS.

The following scenarios where masking is recommended should be considered by compilers;

### 1. Surface features crossing IENC cell boundaries:

When a single feature of type surface crosses the boundaries of adjoining IENC cells, mask the edge where it shares the geometry of the boundary in each IENC:

**Figure 2-6 – Surface feature crossing IENC cell boundaries**

This allows the features to be displayed as a single feature of type surface rather than being divided at the cell boundary and having the representation of two separate features. Note that some IENC production software will automatically truncate (mask) features at the cell boundary.

NOTE: Occasionally an edge of the boundary of an area actually coincides with the IENC cell boundary. Where this occurs and the IENC production system applies automatic truncation (masking) of this edge, the compiler must “unmask” that edge so as to avoid the appearance of the area to be “open ended”.

Where features of type surface extend beyond the entire limit of data coverage for the IENC cell (see clause 3.5), all edges of these area features should be masked:

**Figure 2-7 – Surface features extending beyond the entire limit of data coverage**

Where a cell contains an area of no data coverage and the IENC production software applies automatic truncation (masking) of features extending beyond the limit of data coverage of the IENC, edges of area features extending beyond the internal limit of the area of no data coverage may need to be masked manually.

Table 2-9 below lists those features of type surface that should have edges masked where the boundary of the area crosses or extends beyond the IENC cell limit or the area of data coverage of the IENC cell.

| Feature Type                     | Comment                                                         |
|----------------------------------|-----------------------------------------------------------------|
| Anchorage Area                   |                                                                 |
| Berths                           |                                                                 |
| Bunker Station                   |                                                                 |
| Cable Area                       |                                                                 |
| Cargo Transshipment Area         |                                                                 |
| Caution Area                     | Also edges that are shared with Traffic Separation Scheme (TSS) |
| Communication Area               |                                                                 |
| Dredged Area                     |                                                                 |
| Dumping Ground                   |                                                                 |
| Exceptional Navigation Structure |                                                                 |

| Feature Type                  | Comment                                           |
|-------------------------------|---------------------------------------------------|
| Fishery Zone                  |                                                   |
| Harbour Area (Administrative) |                                                   |
| Harbour Basin                 |                                                   |
| Lock Basin Part               |                                                   |
| Military Practice Area        |                                                   |
| Offshore Production Area      |                                                   |
| Pilotage District             | When the whole cell falls within a pilotage area. |
| Pilot Boarding Place          |                                                   |
| Port Area                     |                                                   |
| Precautionary Area            | Not applied if it is within a TSS.                |
| Quality of Bathymetric Data   |                                                   |
| Quality of Survey             |                                                   |
| Refuse Dump                   |                                                   |
| Restricted Area               |                                                   |
| Sandwave                      |                                                   |
| Seaplane Landing Area         |                                                   |
| Submarine Pipeline Area       |                                                   |
| Terminal                      |                                                   |
| Turning Basin                 |                                                   |
| Vegetation                    |                                                   |
| Vehicle Transfer              |                                                   |
| Vessel Traffic Service Area   |                                                   |
| Water Turbulence              |                                                   |
| Waterway Area                 |                                                   |

**Table 2-9 – Features requiring masking along data coverage limit edges**

## 2. Surface features having Inland ECDIS or ECS symbol pattern fill:

Surfaces symbolised in Inland ECDIS or ECS with a patterned fill, and for which the outer edge of the surface has no significance (or is subject to change or intermittent), for example **Vegetation** (see Figure 2-8 below) or **Water Turbulence** features, may have the boundary of the surface masked to reduce screen clutter.

**Figure 2-8 – Surface feature with pattern fill**

Compilers must take care that the surface is large enough at the optimum display scale of the IENC data (and at smaller optimum display scales at which it is intended that the feature should be displayed) so that at least one pattern symbol is displayed in the area. If this is not the case, the boundary of the surface should not be masked. Alternatively, a point feature may be encoded instead of the surface feature. It may be useful to load and display the IENC in an Inland ECDIS or ECS in order to assist with making decisions as to the best encoding option to adopt in individual circumstances.

### 3. Routing measures – entrance and exit edges:

Routing measures such as Traffic Separation Schemes (TSS) and Two-Way Routes have defined “ends” through which vessels enter and exit the route. Most routing measures also consist of multiple components having different orientations. Where encoded, many of the features comprising the routing measure symbolise along the edges of the area. Where the edges corresponding to the entry/exit points and between individual components of the route have not been masked, the impression of the route as a single routing measure may not be apparent to the Mariner, and cause confusion. Compilers should therefore mask the entry/exit edges, and all edges between components within the routing measure.

Table 2-10 below lists those area features that should have entry/exit edges, and all edges between components within the routing measure masked.

| Feature Type                        | Comment                                                                     |
|-------------------------------------|-----------------------------------------------------------------------------|
| Fairway                             |                                                                             |
| Inshore Traffic Zone                | Only to be applied when the entrance and/or exit routes are known           |
| Recommended Traffic Lane Part       |                                                                             |
| Traffic Separation Scheme lane Part |                                                                             |
| Two-Way Route part                  |                                                                             |
| Coverage                            | Coverage available, mask full coverage. (No Coverage available, don't mask) |
| Navigational System of Marks        | Mask full coverage.                                                         |

**Table 2-10 – Features for masking of entry/exit points**

Figure 2-9 below shows an example of a TSS with all appropriate edges of the components of the TSS masked.

**Figure 2-9 – Traffic Separation Scheme with appropriate masking**

To give an indication of the effect of masking in a complex area such as an area containing a TSS, Figure 2-9 includes a **Caution Area** feature of type surface which has not had its edges masked. Due to the existence of the magenta “!” symbols within the **Caution Area**, and the fact that the edges of the **Caution Area** are coincident with the outer edge of the TSS, it is possible to further reduce Inland ECDIS or ECS display clutter by masking the edges of the **Caution Area**. The resultant Inland ECDIS or ECS display can be seen in Figure 2-10 below.

**Figure 2-10 – Traffic Separation Scheme with masked Caution Area**

NOTE: In the example above it is also possible to mask the areas of water turbulence (indicated in Figure 2-10 by red arrows – see scenario 2 above), however the small area to the east of the West cardinal buoy is too small to display the symbol at the optimum display scale of the IENC data. In cases such as this the compiler should consider capturing this as a **Water Turbulence** feature of type point.

### **2.5.11 Collection Features Extending Beyond Cell Boundaries**

If a collection feature extends beyond a cell boundary (i.e. the features that make up the collection are spread over multiple cells), the collection feature should be repeated in each cell that contains one or more component features. However, only the features that exist in the cell that contains the instance of the collection feature can be referenced by that collection feature. If this technique is used, each instance of the original collection feature must have the same feature identifier (LNAME). It is up to the application (e.g. the Inland ECDIS or ECS) that uses the cells to rebuild the complete collection feature based on the unique feature identifier.

## 2.6 Description of table format for S-401 meta, geo and information features

### X.X Clause heading

| IHO Definition: <b>FEATURE:</b> Definition. (Authority for definition).<br>If there is a deviating definition for inland waterways, it is added here as a remark.                                                                                                                                                                                                                                                                                        |                                                                                                                    |                                                                                                                                                                                |                                    |                                                                                                       |

| This section lists the full list of allowable attributes for the S-401 feature. Sub-attributes (Type prefix (S)) of complex (Type C) attributes are listed in alphabetical order and indented directly under the entry for the complex attribute (see below for example). Note that a complex attribute may have simple or complex attributes as sub-complex attributes.<br><br>Attributes in <i>italics</i> are allowed, but not recommended for IENCs. | This section lists the corresponding IENC attribute acronym. A blank cell indicates no corresponding IENC acronym. | This section lists the allowable encoding values for S-401 (for enumeration (E) Type attributes only). Further information about the attribute is available in Sections 27-30. | Attribute type (see clause 2.4.2). | Multiplicity describes the "cardinality" of the attribute in regard to the feature. See clause 2.4.1. |

| S-401 Role                                                                                                                                                                                                                                                                                                                                                                                                                                               | Association Type                                                                                                   | Associated to                                                                                                                                                                  | Type                               | Multiplicity                                                                                          |

| Role name       | Name of Association (see clause 25.xx) | Feature or Information Type(s)                                                              | Association/ Aggregation/ Composition | 0,1                                                                                                                           |
|-----------------|----------------------------------------|---------------------------------------------------------------------------------------------|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| See Section 26. | See Section 25.                        | Corresponds to the feature(s) that the subject feature may be associated to. See Section 25 | Association type.                     | The individual multiplicity to which the subject feature may be associated to the "Associated to" feature(s) (see clause 25). |

† For each instance of fixed date range, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

The “†” superscript in the Multiplicity column indicates a “conditional” mandatory attribute. See clause 2.4.3.

### **X.X.X Sub-clause heading(s)**

Introductory remarks. Includes information regarding the real world entity/situation requiring the encoding of the Feature in the IENC, and where required nautical cartographic principles relevant to the Feature to aid the compiler in determining encoding requirements.

Specific instructions to encode the feature.

Note that in all sub-clauses feature types and association names are shown in **Bold Capitalised Text**; attributes (complex, sub- and simple) are shown in **bold lower case text**; and attribute values (including enumerate codes) are shown in *italic text*.

#### Remarks:

- Additional encoding guidance relevant to the feature.

### **X.X.X.X Sub-sub-clause heading(s)**

Clauses related to specific encoding scenarios for the Feature. (Not required for all Features).

#### Remarks:

Additional encoding guidance relevant to the scenario (only if required).

Distinction: List of features in the Product Specification distinct from the Feature.

#### Inland specific Encoding Instructions:

- A) inland specific encoding instructions in addition to the instructions copied from S-101 above

#### Remarks:

- S-401 Attribute: Indentation of attributes indicates sub-attributes of complex attributes. Complex attributes may also be sub-attributes of complex attributes, which is indicated by further indentation of the attribute name in the tables.
- S-401 Attribute: Attributes shown in grey text are ECDIS “system” attributes which are populated by the IENC production system in order to assist with portrayal of IENC data in Inland ECDIS or ECS (see Section 30). These attributes may be further edited by the compiler as required.
- IENC Acronym: IENC attribute acronyms shown in italic style text have been re-modelled in S-401 from IENC.

- **Allowable Encoding Value:** For enumeration (EN) type attributes, the enumerate values listed are only those allowable for the particular binding of the attribute relevant to the feature. Allowable values may vary for the attribute depending on the feature to which the attribute is bound. Such bindings are defined in the S-401 Feature Catalogue. The full list of enumerate values that may be assigned to an attribute in S-401 can be found in Sections 27 and 28 of this document.
- **Type:** The prefix (C) indicates that the attribute is a complex attribute. Complex attributes are aggregates of other attributes that can be simple type or complex type. The prefix (S) indicates that the attribute is a sub-attribute of a complex attribute. Complex attributes that are sub-attributes of a complex attribute, and their sub-attributes, are indicated by indentation of the attribute name in the S-401 Attribute column.
- **Feature/Feature, Feature/Information and Spatial/Information associations,** including allowable features for association ends, are described in Section 25.

## 2.7 Inland specific General Guidance

### 2.7.1 Minimum content of an IENC

Each feature has been classified for encoding purposes as mandatory, conditional or optional.

- **Mandatory (M)** features must be encoded.
- **Conditional (C)** features are mandatory (must be encoded) if defined conditions are met. If the defined conditions are not met, the features are **Optional (O)**.
- **Optional (O)** features should be encoded if the value is known.

### 2.7.2 Source Indication

See inland specific encoding instructions in 29.28.

### 2.7.3 Numeric precision

The maximum number of decimals of numeric attributes is defined for each attribute (e.g. XX.dd for maximum two decimals). The encoding of numeric attributes (e.g. of depth information and heights of structures) should reflect the accuracy of the number. For example a bridge height of thirty-five meters, accurate to one meter, has to be encoded as 35, not as 35.0 or 35.00. Measured values without safety margins should be used.

### 2.7.4 Assigning approximate positions

To assign an approximate position ('PA') for charted features, the attribute **quality of horizontal measurement (QUAPOS) = 4** (approximate)] is assigned to the appropriate spatial type (point or curve). It is not assigned to the feature (e.g. **Wreck (WRECKS)** feature), but to the spatial reference for the feature. When correctly coded, the electronic chart system will display 'PA' adjacent to the feature.

### 2.7.5 Legal ECDIS

Category attributes for ship types, ship formations and cargo type are available. These categories are used to describe for which type of ship, convoy, or cargo the particular regulation is valid. There are two ways of describing which categories are affected by the rule:

1. explicit selection
2. implicit selection

The attributes for explicit type selection are used to explicitly select the types from the given list. The attributes for implicit type selection are used to select those types that are not affected.

It is up to the encoder if the explicit attribute or its implicit version is used. However, it is not allowed to use both attributes when defining the category of a law content feature.

One would make use of implicit type selection if for example the respective regulation states which types are excluded from the regulation rather than explicitly listing those types that are affected.

Example: “recreational crafts are excluded from a speed limit.”

### **2.7.6 Collection features extending beyond cell boundaries**

If a collection feature extends beyond a cell boundary (i.e. the features that make up the collection are spread over multiple cells), the collection feature should be repeated in each cell that contains one or more component features. However, only the features that exist in the cell that contains the instance of the collection feature can be referenced by that collection feature. If this technique is used, each instance of the original collection feature must have the same feature identifier (LNAME). It is up to the application (e.g. the Inland ECDIS or ECS) that uses the cells to rebuild the complete collection feature based on the unique feature identifier.

### 3 Metadata Features

The maximum use must be made of Meta features to reduce the attribution on individual features. In a Base dataset (see S-401 Annex B, clause B5), some Meta features are mandatory.

These mandatory Meta features are in the following list:

**Data Coverage:** In order to assist in data discovery, the Meta feature **Data Coverage** must be used to provide coverage of the part of the dataset covered by Skin of the Earth features. See clause 3.5.

**Navigational System of Marks:** The Meta feature **Navigational System of Marks** must provide an exhaustive non-overlapping coverage of the **Data Coverage** feature(s). See clause 3.6.

**Quality of Bathymetric Data:** The Meta feature **Quality of Bathymetric Data** defines areas within which uniform assessment exists for the quality of bathymetric data, and is used to provide an assessment of the overall quality of bathymetric data to the Mariner. Areas of a dataset at optimum display scale 1:700000 and larger containing depth data or bathymetry must be covered by one or more **Quality of Bathymetric Data** features, which may overlap vertically (see clause 3.8.1). At optimum display scales smaller than 1:700000, **Quality of Bathymetric Data** features are optional.

NOTE: Where a dataset does not contain any depth data or bathymetry, it is not required to encode **Quality of Bathymetric Data**.

**Sounding Datum:** The Meta feature **Sounding Datum** must provide an exhaustive non-overlapping coverage of the **Quality of Bathymetric Data** feature(s). See clause 3.9.

NOTE: Where a dataset does not contain any depth data or bathymetry, it is not required to encode **Sounding Datum**.

**Vertical Datum of Data:** The Meta feature **Vertical Datum of Data** must provide an exhaustive non-overlapping coverage of the **Data Coverage** feature(s). See clause 3.10.

#### 3.1 Horizontal uncertainty

The attributes **quality of horizontal measurement** and **horizontal position uncertainty** may be applied to any spatial type, in order to qualify the location of a feature.

If it is required to encode the uncertainty of a horizontal clearance (complex attributes **horizontal clearance fixed** and **horizontal clearance open**), it must be done using the sub-attribute **horizontal distance uncertainty**.

**horizontal distance uncertainty** applies only to **horizontal clearance fixed** and **horizontal clearance open**. There is no attribute to express the accuracy of the attributes **horizontal length** and **horizontal width**.

**horizontal distance uncertainty** and **quality of horizontal measurement** must not be applied to the spatial type of any geo feature if they are identical to the **horizontal distance uncertainty** and **quality of horizontal measurement** values of the underlying Meta feature. **horizontal position uncertainty** must not be applied to the spatial type of any geo feature if it is identical to the **horizontal position uncertainty** value(s) of the underlying Meta feature, except for **Sounding** and **Underwater/Awash Rock** features; and **Foul Ground**, **Marine Farm/Culture**, **Obstruction** and **Wreck** features of type point (see clauses 3.8.1.3, 11.3, 13.4-7 and 13.5).

**quality of horizontal measurement** gives qualitative information, whereas **horizontal position uncertainty** gives quantitative information.

Remarks:

No remarks.

#### 3.2 Vertical uncertainty

If it is required to encode the uncertainty of a vertical clearance (complex attributes **vertical clearance fixed**, **vertical clearance open**, **vertical clearance closed** and **vertical clearance safe**), it must be done using the complex sub-attribute **vertical uncertainty** (see clause 29.42).

If several vertical clearances are given for one feature, the uncertainty given must be that of the least accurate.

Remarks:

No remarks.

### 3.3 Hierarchy of metadata

The following Table indicates individual feature attributes that supersede meta feature attributes.

| Meta feature class              | Meta feature attribute            | Geo feature attribute                                                                                |
|---------------------------------|-----------------------------------|------------------------------------------------------------------------------------------------------|
| Navigational System of Marks    | marks navigational – system of    | marks navigational – system of                                                                       |
| Quality of Bathymetric Data     | horizontal position uncertainty*  | horizontal position uncertainty**                                                                    |
| Quality of Bathymetric Data     | vertical uncertainty*             | vertical uncertainty                                                                                 |
| Quality of Bathymetric Data     | vertical uncertainty*             | vertical uncertainty**                                                                               |
| Quality of Non-Bathymetric Data | horizontal distance uncertainty   | horizontal clearance fixed, horizontal clearance open                                                |
| Quality of Non-Bathymetric Data | horizontal position uncertainty   | horizontal position uncertainty**                                                                    |
| Quality of Non-Bathymetric Data | orientation uncertainty           | orientation uncertainty                                                                              |
| Quality of Non-Bathymetric Data | vertical uncertainty              | vertical clearance closed, vertical clearance fixed, vertical clearance open, vertical uncertainty** |
| Quality of Survey               | quality of horizontal measurement | quality of horizontal measurement**                                                                  |
| Quality of Survey               | quality of vertical measurement   | quality of vertical measurement                                                                      |
| Quality of Survey               | technique of vertical measurement | technique of vertical measurement                                                                    |
| Vertical Datum of Data          | vertical datum                    | vertical datum                                                                                       |

**Table 3-1 – Hierarchy of metadata**

\* The information type **Spatial Quality**, attributes **horizontal position uncertainty** and **vertical uncertainty**, may be associated to **Quality of Bathymetric Data** using the information to feature association **Quality of Bathymetric Data Composition** (see clause 25.9).

\*\* As populated on an associated instance of the information type **Spatial Quality**, using the information to feature association **Spatial Association** (see clause 25.10).

Features and attributes shown in grey text in Table 3-1 above do not play an active role in regard to Inland ECDIS or ECS display and/or performance in terms of hierarchy of the encoding. However, where both the S-401 Meta feature and the attribute for the Geo feature are encoded, end-user interpretation of the Inland ECDIS or ECS Pick Report is that the value populated for the attribute on the Geo feature provides the relevant value.

It is prohibited to use an attribute on an individual feature, if this attribute has the same value as the general value defined by the Meta feature.

### 3.4 Quality of non-bathymetric data

|                                                                                                                                                                                                                                          |                                  |                                                                                       |             |                     |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|---------------------------------------------------------------------------------------|-------------|---------------------|
| <b>IHO Definition: QUALITY OF NON-BATHYMETRIC DATA.</b> An area within which a uniform assessment of the quality of the non-bathymetric data exists. (Adapted from S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.208, November 2000). |                                  |                                                                                       |             |                     |

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 3.4.1 Quality of non-bathymetric data

The Meta feature **Quality of Non-Bathymetric Data** may be used to provide an indication of the overall uncertainty of position for all non-bathymetric features. It must not be used to provide the uncertainty of bathymetric information.

**horizontal position uncertainty** on the **Quality of Non-Bathymetric Data** applies to non-bathymetric data situated within the area, while **quality of horizontal measurement** or **horizontal position uncertainty** on the associated spatial types qualifies the location of the **Quality of Non-Bathymetric Data** feature itself.

#### Remarks:

- No remarks.

Distinction: Quality of Bathymetric Data; Quality of Survey.

#### Inland specific Encoding Instructions:

- The information in the attributes may be applied to any spatial type, in order to qualify the location of a feature.
- The attributes must not be applied to the spatial type of any geo feature if they are identical to the values of the underlying meta feature.
- Meta features Quality of Non-bathymetric Data and Quality of Bathymetric Data should not overlap.
- The accuracy of data is only encoded in areas where accuracy of data is available and clearly defined.

### 3.5 Data coverage

IHO Definition: **DATA COVERAGE.** A geographical area that describes the coverage and extent of spatial objects. (S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.210, November 2000).

**S-401 Metadata Feature: Data Coverage (M\_COVR) (M\_CSCL) (M)**

**Primitives: Surface**

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 3.5.1 Coverage

The Meta feature **Data Coverage** encodes the area covered by data within the dataset. This feature can also be used to provide the Inland ECDIS or ECS with the scale information necessary for the determination of dataset loading and rendering (display) in relation to the user selected viewing scale in the Inland ECDIS or ECS. There must be a minimum of one **Data Coverage** feature in the dataset.

**Data Coverage** features must cover the equivalent area to the extent of the spatial types in the dataset, and must not overlap (see clause 2.5.1).

Where populated, all **Data Coverage** features in the dataset must have the same value for the attribute **drawing index**, as datasets that share a common drawing index are intended to form a seamless presentation, regardless of the populated value(s) for minimum display scale. **Data Coverage** features which share a common drawing index must not overlap.

The attribute **optimum display scale** is used to indicate the intended viewing scale for the data. The value populated for **optimum display scale**, therefore, provides a reference for the user selected viewing scale in the Inland ECDIS or ECS at which the overscale warning will be displayed as the boatmaster continues to zoom in if there is no larger optimum display scale IENC dataset available.

The attribute **minimum display scale** is used to indicate the smallest intended viewing scale for the data where a full portfolio of IENCs is available; and provides the reference scale that defines a “series” of IENCs covering a geographic area intended to be displayed seamlessly. Where an empty (null) value is populated for **minimum display scale**, the Inland ECDIS or ECS will continue to display the data regardless of how small the user selected viewing scale becomes. The value populated for **minimum display scale**, therefore, is intended to be used in a series of IENC cells covering a geographic area to determine the dataset rendering (display) priority as the user selected viewing scale becomes larger.

The mandatory attribute **maximum display scale** is used to indicate the scale at which the Data Producer considers that the “grossly overscaled” warning is to be triggered based on the user selected viewing scale.

For IENC, in order to provide a consistent relationship between the encoded data and the way the data is displayed in Inland ECDIS or ECS, the values for minimum display scale and optimum display scale can be taken from the values listed in the following Table:

| Scale                                                                                                      |
|------------------------------------------------------------------------------------------------------------|
| NULL (only allowed on minimum display scale (data will continue to be displayed at the next larger scale)) |
| 1:10,000,000                                                                                               |

| 1:200 (only allowed on optimum and maximum display scale)                                                  |

**Table 3-2 – Optimum and minimum display scale values**

[NOTE: The selection of values for **maximum display scale** and **minimum display scale** for any selected **optimum display scale** are at the discretion of the Data Producer. That is, any value listed for **maximum display scale** and **minimum display scale** above may be selected from any of the listed values, with the only restriction being that **maximum display scale** must be a smaller value than/equal to **optimum display scale** which must be a smaller value than **minimum display scale** (or any value if **minimum display scale** is populated with an empty (null) value).]

Typically, only a single **Data Coverage** feature should be used in a dataset. However, if the optimum display scale is different for discrete areas within a single IENC dataset, this must be indicated by encoding separate, non-overlapping **Data Coverage** features, each having a different value populated for **optimum display scale**. Producing Authorities are to note, however, that excessive use of multiple **Data Coverage** features having different values of **optimum display scale** within a single dataset should be avoided. Where different values of **optimum display scale** are used, this should be restricted only to data compiled in order to achieve the intended navigational usage for the entire dataset. Datasets must have the same value for **minimum display scale** for all **Data Coverage** features in the dataset. Datasets may have different values populated for **maximum display scale** for the **Data Coverage** features in the dataset; these values are typically populated as the value corresponding to 2 x the scale (or half the denominator) value populated for **optimum display scale** (this will replicate the corresponding gross overscale indication as implemented in S-57/S-52), but are at the discretion of the Data Producer. For example, the value for **maximum display scale** may be set to the same value as **optimum display scale** to have the “grossly overscaled” warning appear at any larger user selected viewing scale than **optimum display scale**; or populated as the value corresponding to the **minimum display scale** value for the next largest scale dataset(s) in the IENC portfolio.

Where a series of differing optimum display scale IENC datasets are compiled covering the same geographic area, the smallest scale value populated for **optimum display scale** for **Data Coverage** feature(s) in the dataset should correspond to the **minimum display scale**, where populated, for the next largest optimum display scale IENC dataset. The largest scale value populated for **optimum display scale** for **Data Coverage** feature(s) in the dataset must not be a larger scale value than the optimum display scale for the next largest optimum display scale IENC dataset, where such a dataset exists.

Remarks:

- This Meta feature is intended to support an indication of coverage; and facilitates the loading and rendering (display) of datasets in the end-user system.
- Where more than one **Data Coverage** feature exists for a dataset, the dataset, when initially loaded, will be displayed in the Inland ECDIS or ECS at a display scale corresponding to the largest scale value populated for **optimum display scale**.
- Where a dataset consists of only one **Data Coverage** feature, the value for the optimum display scale populated in the dataset discovery metadata must be the same as the value populated for **optimum display scale** on the **Data Coverage**.
- Except for the largest scale dataset coverage, datasets with multiple **Data Coverage** features must not have excessive differences in the values populated for **optimum display scale** between the **Data Coverage** features. Typically, this should be interpreted as there being no more than one scale step value as defined in Table 3-2 above between the **optimum display scale** values in a single dataset.

Distinction:

Inland specific Encoding Instructions:

- A) All spatial features in an IENC must be covered by a **Data Coverage** (M\_COVR) with **category of coverage** (CATCOV) = 1 (coverage available) surface feature.
- B) US & RU: The use of **category of coverage** (CATCOV) = 2 (no coverage available) is required
- C) EUR: The use of **category of coverage** (CATCOV) = 2 (no coverage available) is optional

### 3.6 Navigational system of marks

**IHO Definition: NAVIGATIONAL SYSTEM OF MARKS.** An area within which the navigational system of marks has been established in relation to a specific direction. (Adapted from S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.214, November 2000).

#### **S-401 Metadata Feature: Navigational System of Marks (*m\_nsys*) (M)**

#### Feature Associations

| S-401 Role         | Association Type                              | Associated to             | Type        | Multiplicity |
|--------------------|-----------------------------------------------|---------------------------|-------------|--------------|
| The Updated Object | <b>Updated Information</b> (see clause 25.16) | <b>Update Information</b> | Association | 0,*          |
| -                  | <b>Spatial Association</b> (see clause 25.10) | <b>Spatial Quality</b>    | Association | 0,*          |

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 3.6.1 Buoyage systems

The buoyage system of the dataset must be encoded using the Meta feature **Navigational System of Marks**:

All parts of the dataset containing data must be covered by **Navigational System of Marks** features, with the attribute **marks navigational – system of** indicating the buoyage system in operation. **Navigational System of Marks** features must not overlap.

Individual buoys and beacons may not be part of the general buoyage system. This should be encoded using the attribute **marks navigational – system of** on these buoy and beacon features.

Remarks:

- For guidance regarding the encoding of aids to navigation in the IALA maritime buoyage system, see clause 18.3.1.1.
- If it is required to encode an area within which the navigational system of marks has been established in relation to a specific direction, it must be done using the feature **Local Direction of Buoyage** (see clause 3.7).

Distinction: Local Direction of Buoyage.

Inland specific Encoding Instructions:

- A) The Metadata Feature **Navigational System of Marks** (m\_nsys) surface should only cover those areas that contain IENC data.
- B) US: All inland waterways in the United States use IALA B.
- C) EUR: In areas with mixed systems (IALA-A and main European inland waterway marking system) code **marks navigational – system of** (MARSYS) according to majority of marks and code individual deviant marks at feature level to the appropriate system.
- D) RU: All inland waterways in Russia use **marks navigational – system of** (MARSYS) = 12 (Russian inland waterway regulations).
- E) BR: All national inland waterways in Brazil use **marks navigational – system of** (MARSYS) = 13 (Brazilian national inland waterway regulations). In areas with mixed systems (IALA B and one above) use **marks navigational – system of** (MARSYS) = 2 (IALA B) and code individual deviant marks to the appropriate system (MARSYS = 13 or 14).
- F) BR: Paraguai-Parana International Waterway: In Brazilian extent, use **marks navigational – system of** (MARSYS) = 2 (IALA B) and code Brazilian complementary aids with MARSYS = 15 (Paraguai-Parana waterway - Brazilian complementary aids).

### 3.7 Local direction of buoyage

**IHO Definition: LOCAL DIRECTION OF BUOYAGE.** An area within which the navigational system of marks has been established in relation to a specific direction. (Adapted from S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.214, November 2000).

#### **S-401 Metadata Feature: Local Direction of Buoyage (*m\_nsys*) (C)**

##### **Primitives: Surface**

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 3.7.1 Local direction of buoyage

**Figure 3-1 – Buoyage system and direction**

Within a dataset, there may be some areas where the direction of buoyage is defined by local rules and must, therefore, be specified. If required, these areas must be encoded as **Local Direction of Buoyage** features, with the mandatory attribute **orientation value** indicating the direction of buoyage. **Local Direction of Buoyage** features must not overlap, but in areas where local buoyage directions apply, **Local Direction of Buoyage** features must overlap **Navigational System of Marks** features (see clause 3.6) (see Figure 3-1 above).

#### Remarks:

The mandatory attribute **marks navigational – system of** is required for Inland ECDIS or ECS portrayal, and must be populated with the same value as populated for the **marks navigational – system of** on the underlying **Navigational System of Marks** feature.

#### Distinction:

Navigational System of Marks.

#### Inland specific Encoding Instructions:

- A) EUR: This feature is used to encode the local direction of buoyage for waterways without a defined direction, for example intertidal creeks.
- B) EUR: For bendy intertidal creeks it may be necessary to encode several Metadata Features **Local Direction of Buoyage** with appropriate **orientation values** (ORIENT) to ensure that the displayed arrow aligns with creek axis.

### 3.8 Quality of bathymetric data

**IHO Definition: QUALITY OF BATHYMETRIC DATA.** An area within which a uniform assessment of the quality of the bathymetric data exists. (S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.216, November 2000).

**S-401 Metadata Feature: Quality of Bathymetric Data (M\_QUAL) (O)**

**Primitives: Surface**

### Feature Associations

| S-401 Role         | Association Type                                                 | Associated to             | Type        | Multiplicity |
|--------------------|------------------------------------------------------------------|---------------------------|-------------|--------------|
| -                  | <b>Quality of Bathymetric Data Composition</b> (see clause 25.9) | <b>Spatial Quality</b>    | Association | 0,*          |
| The Updated Object | <b>Updated Information</b> (see clause 25.16)                    | <b>Update Information</b> | Association | 0,*          |
| -                  | <b>Spatial Association</b> (see clause 25.10)                    | <b>Spatial Quality</b>    | Association | 0,*          |

† The sub-complex attribute **fixed date range** is mandatory if more than one instance of the complex attribute **zone of confidence** is encoded.

The sub-complex attributes **horizontal position uncertainty** and **vertical uncertainty** are mandatory if the **Quality of Bathymetric Data** instance is not associated to a **Spatial Quality** instance using the association **Quality of Bathymetric Data Composition**.

For each instance of fixed date range, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

### 3.8.1 Quality, reliability and uncertainty of bathymetric data

Information about quality, reliability and uncertainty of bathymetric data is given using:

- the Meta feature **Quality of Bathymetric Data** and, if required, an associated instance of the Information type **Spatial Quality** (see clause 24.5) for an overall assessment of the quality of bathymetric data;
- the Meta feature **Quality of Survey** for additional information about individual surveys (see clause 3.11);
- the attributes **quality of vertical measurement** and **technique of vertical measurement** on groups of soundings or individual features;
- the attributes **horizontal position uncertainty**, **quality of horizontal measurement** and **vertical uncertainty** on the spatial types (see clauses 2.4.7 and 24.5).

Bathymetric data quality comprises the following:

- completeness of data (for example, seafloor coverage);
- currency of data (for example, temporal degradation);
- uncertainty of data;
- source of data.

For the boatmaster, **Quality of Bathymetric Data** provides the most useful information. Therefore, the use of **Quality of Bathymetric Data** is mandatory for areas containing depth data or bathymetry on IENC datasets at optimum display scale 1:700000 and larger.

In order to provide an indication of the horizontal position and vertical accuracies of the features to which it applies, instances of **Quality of Bathymetric Data** must have the sub-complex attributes **horizontal position uncertainty** and **vertical uncertainty** populated on **Quality of Bathymetric Data**, or alternately on an associated instance of the information type **Spatial Quality** (see clause 24.5), using the association **Quality of Bathymetric Data Composition** (see clause 25.9).

More detailed information about a survey may be given using **Quality of Survey** (see clause 3.11). For example, in incompletely surveyed areas, lines of passage soundings may be indicated as such using a curve **Quality of Survey** feature. This information is more difficult for the boatmaster to interpret, therefore the use of **Quality of Survey** is optional.

For individual features (wrecks, obstructions etc), or individual/small groups of soundings, **quality of vertical measurement**, **technique of vertical measurement**, **horizontal position uncertainty** and **vertical uncertainty** may be used to provide additional information about quality and uncertainty.

The Meta feature **Quality of Bathymetric Data** defines areas within which uniform assessment exists for the quality of bathymetric data, and must be used, where required, to provide an assessment of the overall quality of bathymetric data to the boatmaster. Therefore, areas of a dataset containing depth data or bathymetry at optimum display scale 1:700000 and larger may be covered by one or more **Quality of Bathymetric Data**, which may overlap vertically in order to define the quality of bathymetric data at varying depths in the water column.

**Figure 3-2 – Adjoining and overlapping Quality of Bathymetric Data features**

The Figure 3-2 above demonstrates the encoding for varying quality of bathymetric data in the water column, in this example a mechanically swept area to a depth of 5 metres that has also been previously surveyed using single beam echo sounder to the seabed. For the **Quality of Bathymetric Data** feature that defines the data quality for the swept area, it is important to note that the recommended attribution shown above is intended to provide the highest (best) quality indicator for vessels navigating at a safety depth of less than 5 metres in the area. For vessels navigating at a safety depth of greater than 5 metres in the area, or at any depth outside the area, the lower quality indicator will be provided.

**NOTE:** Figure 3-2 demonstrates the two options for the encoding of the horizontal position and vertical uncertainties available in S-401. For the area covered by the swept area, the varying horizontal position and vertical uncertainties in the water column are encoded using the sub-complex attributes **horizontal position uncertainty** and **vertical uncertainty** on the **Quality of Bathymetric Data** features. For the two areas covered only by the single beam echo sounder survey to the seabed, the horizontal position and vertical uncertainties are encoded using the sub-complex attributes **horizontal position uncertainty** and **vertical uncertainty** on an associated **Spatial Quality** feature (which may be a single **Spatial Quality** feature associated to both **Quality of Bathymetric Data** features). See the Remarks below and clause 24.5.

Remarks:

- The mandatory attribute **data assessment** provides an overall indicative level of assessment of bathymetric data from which further attribution is derived, and assists with portrayal of bathymetric data quality information in Inland ECDIS or ECS:
  - Where the value for **data assessment** is set to 1 (assessed), all additional attribution for the **Quality of Bathymetric Data** feature must be indicative of the quality of bathymetric data for the area.
  - Where the value for **data assessment** is set to 2 (assessed (oceanic)), all additional attribution for the **Quality of Bathymetric Data** feature should be indicative of the quality of bathymetric data for the area for a boatmaster's Inland ECDIS or ECS pick report, however no portrayal of the quality information will display on the Inland ECDIS or ECS. This value should only be used to cover open ocean (oceanic) depths in waters deeper than 200 metres.
  - Where the value for **data assessment** is set to 3 (unassessed), the mandatory attributes **category of temporal variation** = 6 (unassessed); **features detected** (least depth of detected features measured and significant features detected) = *False*; **full seafloor coverage achieved** = *False*; and **category of zone of confidence in data** = 6 (zone of confidence U); and **horizontal position uncertainty** (uncertainty fixed) and **vertical uncertainty** (uncertainty fixed) on **Quality of Bathymetric Data** or the associated **Spatial Quality** = empty (null) must be populated.
- Wherever possible, meaningful and useful values for the attributes **category of temporal variation**, **full seafloor coverage achieved**, and the complex attribute **features detected** must be used for areas of bathymetry. For areas of unstable seafloors, the complex attribute **survey date range** (date end) should be used to indicate the date of the survey of the underlying bathymetric data.
- As a result of some disasters, for example earthquakes, tsunamis, hurricanes, it is possible that large areas of seafloor have moved and/or become cluttered with dangerous obstructions. Emergency surveys may subsequently be conducted over essential shipping routes and inside harbours. Outside these surveys, all existing detail is now suspect, whatever the quality of the previous surveys. In such cases, the attribute **category of temporal variation** should be reclassified to value 1 (extreme event), the Boolean attribute **full seafloor coverage achieved** set to *False*; complex attribute **features detected**, Boolean sub-attributes **least depth of detected features measured** and **significant features detected** set to *False*; the **zone of confidence** sub-attribute **category of zone of confidence in data** reclassified to 5 (zone of confidence D); and the sub-attributes **horizontal position accuracy** (uncertainty fixed) and **vertical uncertainty** (uncertainty fixed) on **Quality of Bathymetric Data** or the associated **Spatial Quality** populated with an empty (null) value in the affected areas outside the area covered by emergency surveys.
- To express completeness of bathymetric data, the complex attribute **features detected** must be encoded. **features detected** indicates that a systematic method of exploring the seafloor, or the water column to the depth indicated by population of the attribute **depth range maximum value**, was undertaken to detect significant features. The sub-attributes **size of features detected** and **least depth of detected features measured** must not be encoded unless the sub-attribute **significant features detected** is set to *True*.
- The mandatory complex attribute **zone of confidence** is used on a **Quality of Bathymetric Data** feature to provide an overall indication of the accuracy of the bathymetric data in the area; and may be used to specify the vertical and horizontal position uncertainty of the depths covered by the surface. Where **category of temporal variation** is set to values 2 (likely to change and significant shoaling expected) or 3 (likely to change but significant shoaling not expected), multiple instances of the complex attribute **zone of confidence** should be encoded to provide an indication of the degradation of the overall accuracy as well as the vertical and horizontal position uncertainty of the charted bathymetric information over time.
  - Wherever possible, meaningful and useful values of the mandatory sub-attribute **category of zone of confidence in data** should be used (that is, values other than **category of zone of confidence in data** = 6 (zone of confidence U)) for areas of bathymetry. These values must be

determined from the **category of zone of confidence in data** definition table (see clause 27.102) in accordance with the values populated for the attribute **full seafloor coverage achieved**, the complex attribute **features detected** and the sub-complex attributes **horizontal position uncertainty** and **vertical uncertainty** on the **Quality of Bathymetric Data** or the associated **Spatial Quality** (see the following Remarks bullet).

- The sub-complex attribute **fixed date range** is used to define the date range(s) where the quality is degraded over time. Where multiple date ranges are specified, the **date start** of an instance must be equal to the **date end** of the previous instance. Within the sequence, the **date start** of the first instance and the **date end** of the last instance should not be populated; the values populated for **fixed date range** must not result in the removal of the indication of bathymetric data quality for an area from the boatmaster.
- The sub-complex attributes **horizontal position uncertainty** and **vertical uncertainty** must be encoded using either **Quality of Bathymetric Data** or the Information feature **Spatial Quality** (see clause 24.5). The decision as to which option to use should be based on whether the horizontal position and vertical uncertainty values are specific to a single **Quality of Bathymetric Data** feature or relates to multiple **Quality of Bathymetric Data** features. In general, specific values are related to areas of changeable bathymetry over time or varying bathymetric data quality in the water column (as shown in Figure 3-2 above); and repeating values are specific to general quality uncertainty values in non-changeable areas. It is prohibited to use both options for a single **Quality of Bathymetric Data** instance.
  - **vertical uncertainty** on the **Quality of Bathymetric Data** or the associated **Spatial Quality** is used to specify the vertical uncertainty of the depths covered by the surface within a specified date range (where encoded); and should be adjusted to indicate the degradation of the vertical uncertainty over time where multiple instances of **zone of confidence** are encoded (see above bullet). When **depth range minimum value** is specified on **Quality of Bathymetric Data**, **vertical uncertainty** refers only to the uncertainty of the swept depth defined by **depth range minimum value**.
  - **horizontal position uncertainty** on the **Quality of Bathymetric Data** or the associated **Spatial Quality** is used to specify the positional uncertainty of the depths covered by the surface within a specified date range (where encoded); and should be adjusted to indicate the degradation of the horizontal position uncertainty over time where multiple instances of **zone of confidence** are encoded (see above).
- **depth range minimum value** must only be used on a **Quality of Bathymetric Data** feature where a swept area occupies the entire **Quality of Bathymetric Data** surface, or **Quality of Bathymetric Data** features overlap. Where these features overlap such that varying bathymetric data qualities exist at different depths in the water column, the **depth range minimum value** for a **Quality of Bathymetric Data** must be set to a value 0.1 metres deeper than the **depth range maximum value** for the **Quality of Bathymetric Data** feature defining the quality for the level above; and the topmost **Quality of Bathymetric Data** must have **depth range minimum value** set to an empty (null) value (see Figure 3-2 above).
- **depth range maximum value** must only be used on a **Quality of Bathymetric Data** feature to specify the maximum depth to which all other attributes for the **Quality of Bathymetric Data** feature applies. When **depth range maximum value** is specified, values populated for all other attributes apply only to depths equal to or shoaler than **depth range maximum value**. No quality information is provided for depths deeper than **depth range maximum value**. Where **Quality of Bathymetric Data** features overlap such that varying bathymetric data qualities exist at different depths in the water column, the **depth range maximum value** for a **Quality of Bathymetric Data** must be set to a value 0.1 metres shoaler than the **depth range minimum value** for the **Quality of Bathymetric Data** feature defining the quality for the level below; and the bottommost **Quality of Bathymetric Data** must have **depth range maximum value** set to an empty (null) value (see Figure 3-2 above).
- **Quality of Bathymetric Data** must be encoded over **Unsurveyed Area** features that contain any depth data or bathymetry (depth contours, obstructions, soundings, underwater rocks, wrecks); and must have mandatory attributes **data assessment** = 1 (assessed) **category of temporal**

**variation** = 6 (unassessed); **features detected** (least depth of detected features measured and significant features detected) = *False*; **full seafloor coverage achieved** = *False*; and **zone of confidence** (category of zone of confidence in data) = 5 (zone of confidence D). The **vertical uncertainty** (uncertainty fixed) and **horizontal position uncertainty** (uncertainty fixed) for the **Quality of Bathymetric Data** or the associated **Spatial Quality** should be populated with an empty (null) value.

- For **Unsurveyed Area** features that do not contain any depth data or bathymetry, it is not required to encode a **Quality of Bathymetric Data** feature that covers the area.
- If the attribute **technique of vertical measurement** is required, it must be encoded on either the Meta feature **Quality of Survey** (see clause 3.11) or on individual geo features (for example **Sounding**).
- When the **Quality of Bathymetric Data** surface contains data from only one survey, the date of survey should be specified using the complex attribute **survey date range**, sub-attribute **date end**. When the **Quality of Bathymetric Data** surface contains data from two or more surveys, the date of the most recent and the oldest survey should be specified using the complex attribute **survey date range**.
- **Quality of Bathymetric Data** areas must not be encoded over land.
- **Spatial Quality** (**horizontal position uncertainty**) associated to the **Quality of Bathymetric Data** using the association **Quality of Bathymetric Data Composition** (see clause 25.9), where encoded, applies to bathymetric data situated within the surface, while **Spatial Quality** (**quality of horizontal measurement**) or (**horizontal position uncertainty**) on the associated spatial types using the association **Spatial Association** (see clause 25.10) qualifies the location of the **Quality of Bathymetric Data** feature itself.
- Meta features **Quality of Bathymetric Data** and **Quality of Non-Bathymetric Data** may overlap.
- Additional quality information may be given using the Meta feature **Quality of Survey**.

### 3.8.1.1 Temporal variation

The indication of degrading quality of bathymetry over time should be encoded using multiple instances of the complex attribute **zone of confidence** where required (see 5<sup>th</sup> to 8<sup>th</sup> bullet points in clause 3.8.1 above).

The changeability of the bathymetry must be encoded using **category of temporal variation**. In order for a time reference to be given for the expression of temporal variation, the relevant dates of the bathymetric data should be encoded using the complex attribute **survey date range** if **category of temporal variation** is set to 1 (extreme event), 2 (likely to change and significant shoaling expected) or 3 (likely to change but significant shoaling not expected). Consideration should be given, in particular, for the encoding of **survey date range** if multiple instances of **zone of confidence** are not encoded to provide an indication of the degradation of the overall accuracy of the charted bathymetric information over time, in order to provide the Mariner with a temporal frame of reference for decision making.

### 3.8.1.2 Feature detection

In the context of bathymetry, a feature is any object, whether manmade or not, projecting above the seafloor, which may be considered a danger to surface navigation. Refer to IHO Publication S-44.

The ability to detect bathymetric features must be encoded using the complex attribute **features detected**. The sub-attribute **significant features detected** indicates whether the survey was capable of detecting features of a size indicated by the sub-attribute **size of features detected**. The sub-attribute **least depth of detected features measured** indicates whether the least depth of detected features was found. For instance, if a wreck was found, but it is not certain that the least depth of that wreck was measured, **least depth of detected features measured** must be set to *False*.

### 3.8.1.3 Sounding uncertainty

Sounding uncertainty is encoded using the complex attribute **zone of confidence**, sub-complex attribute **vertical uncertainty** on **Quality of Bathymetric Data**; or alternatively using an associated instance of the information type **Spatial Quality**, complex attribute **spatial accuracy** (see clause 24.5) and using the association **Quality of Bathymetric Data Composition** (see clause 25.9). If it is required to encode additional sounding uncertainty information, it must be done using the attributes **quality of vertical measurement** and **technique of vertical measurement** on groups of soundings or individual features; or by associating another instance of the information type **Spatial Quality** to the spatial type associated with the individual geo features.

The vertical and horizontal position uncertainty values populated on the instance of **Quality of Bathymetric Data** or the associated **Spatial Quality** must reflect the most commonly associated values for the **Obstruction**, **Sounding**, **Underwater/Awash Rock** and **Wreck** features within the area.

Distinction: Quality of Non-Bathymetric Data; Quality of Survey; Spatial Quality.

#### Inland specific Encoding Instructions:

- A) The **Quality of Bathymetric Data** (M\_QUAL) surface should only cover those areas that contain IENC data.
- B) US: Refer to ZOC table in 29.44 for a description of categories.
- C) RU: Currently all IENCs are coded with **category of zone of confidence in data** (CATZOC)=1
- D) The vertical uncertainty for soundings is only given in those areas where detailed depth information is provided. The Metadata Feature shares the geometry with those surfaces.
- E) **Technique of vertical measurement** (TECSOU) has to be used to give the technique of the sounding measurement.
- F) **Vertical uncertainty** (SOUACC) should be used to give information about the accuracy of the sounding data.
- G) **Horizontal position uncertainty** (POSACC) should be used to give information about the accuracy of a position.

### 3.9 Sounding Datum

|                                                                                                                                                                                                                                                                                                                 |                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |             |                     |

| <b>IHO Definition: SOUNDING DATUM.</b> The horizontal plane or tidal datum to which soundings have been reduced. Also called datum for sounding reduction. (Adapted from IHO Dictionary – S-32).<br>The <b>Sounding Datum</b> for inland waterways is in most cases not a horizontal plane but a sloping plane. |                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |             |                     |

|--------------------|--------------------------------------------------|---------------------------|-------------|--------------|
| The Updated Object | <b>Updated Information</b><br>(see clause 25.16) | <b>Update Information</b> | Association | 0,*          |
| -                  | <b>Spatial Association</b><br>(see clause 25.10) | <b>Spatial Quality</b>    | Association | 0,*          |

† For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

### 3.9.1 Sounding datum

For depth information that is encoded using the attributes **value of sounding**, **depth range minimum value**, **depth range maximum value** and **value of depth contour** the sounding datum is encoded using the Meta feature **Sounding Datum**, and must be constant over large areas.

All parts of the dataset containing depth data or bathymetry must be covered by **Sounding Datum** features, with the attribute **vertical datum** indicating the sounding datum. **Sounding Datum** features must not overlap.

For sounding features (**Sounding**) both the position and depth information is encoded by means of coordinates, with the depth information stored in the Z-coordinate. The sounding datum is defined by the Coordinate Reference System (CRS) for the Z-Coordinate ("Coordinate in Z Axis" [ZCOO] subfield of the "3-D Integer Coordinate Tuple" [C3IT] field or the "3-D Integer Coordinate List" [C3IL] field).

The definition of the CRS is stored in the "Dataset Coordinate Reference System" record and referred by the "Vertical CRS Id" [VCID] subfield of the "3-D Integer Coordinate Tuple" [C3IT] field or the "3-D Integer Coordinate List" [C3IL] field.

The CRS for the Z-coordinate should also have the subfield "Axis Type" [AXTY] of the corresponding "Coordinate System Axes" [CSAX] field set to 12 (Gravity Related Depth).

Note, that because every ZCOO value is explicitly linked to sounding datum there is no default value.

#### Remarks:

- The default sounding datum of the dataset must be encoded using the Meta feature **Sounding Datum**, and must be equivalent to the definition of the CRS as stored in the "Dataset Coordinate Reference System" record for the dataset.
- If an area of the dataset is referenced to a different sounding datum than the default, a separate **Sounding Datum** feature must be encoded. All parts of the dataset covered by **Quality of Bathymetric Data** features (see clause 3.8) must be covered by **Sounding Datum** features, with the attribute **vertical datum** indicating the sounding (depth) datum.

- The vertical CRS encoded in the Coordinate Reference System record fields for soundings is not utilized by the Inland ECDIS or ECS in conveying the sounding datum information for an IENC to the boatmaster in Inland ECDIS or ECS. This information is provided instead using **Sounding Datum**. See also S-401 Product Specification Main document, clause 5.3.
- Sounding groups, depth contours and depth areas going across areas having different values of sounding datum must be split at the border of those areas. Other features that should be split include **Marine Farm/Culture**, **Obstruction** and **Wreck**, but only where the value of **value of sounding** is known; and **Berth**, **Cable Submarine**, **Deep Water Route Centreline**, **Deep Water Route Part**, **Dredged Area**, **Dry Dock**, **Fairway**, **Floating Dock**, **Gate**, **Pipeline Submarine/On Land**, **Recommended Route Centreline**, **Recommended Track**, **Two-Way Route Part** and **Quality of Bathymetric Data**, but only if the value of **depth range minimum value** and/or **depth range maximum value** is known.
- Meta features **Sounding Datum** and **Vertical Datum of Data** may overlap.  
Distinction: Vertical Datum.

Inland specific Encoding Instructions:

- A) The areas covered by these Metadata Features must be mutually exclusive.
- B) Depth contours and depth areas going across areas which have different values of Sounding Datum, must be divided into several Features at the border of these Metadata Features.
- C) The sounding datum must be constant over large areas. It applies to the attributes **value of sounding** (VALSOU), **depth range minimum value** (DRVAL1), **depth range maximum value** (DRVAL2) and **value of depth contour** (VALDCO).

### 3.10 Vertical datum of data

**IHO Definition: VERTICAL DATUM OF DATA.** Any level surface (for example Mean Sea Level) taken as a surface of reference to which the elevations within a data set are reduced. Also called datum level, reference level, reference plane, levelling datum, datum for heights. (Adapted from IHO Dictionary – S-32).

The **Vertical Datum of Data** for inland waterways is in most cases not a horizontal plane but a sloping plane.

#### **S-401 Metadata Feature: Vertical Datum of Data (m\_vdat) (O)**

##### **Primitives: Surface**

† For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

### 3.10.1 Vertical datum

Vertical (height) datum information is encoded using the Meta feature **Vertical Datum of Data**, or by populating the attribute **vertical datum** on individual geo features. The values encoded in the attributes **elevation**, **height**, **vertical clearance closed**, **vertical clearance fixed**, **vertical clearance open** and **vertical clearance safe** (positive values up) are referenced to the specified datum(s). **vertical datum** must not be encoded on any geo feature instance unless at least one of the above attributes is also encoded on that feature.

The vertical datum of the dataset must be encoded using the Meta feature **Vertical Datum of Data**:

All parts of the dataset containing data must be covered by **Vertical Datum of Data** features, with the attribute **vertical datum** indicating the vertical (height) datum. **Vertical Datum of Data** features must not overlap.

Various height datums may be used within an IENC. For example, different datums may be used for the following:

- altitude of spot heights, height contours, landmarks,
- elevation of lights,
- vertical clearance.

Where different vertical datums are used for the various vertical measurements, the default value given in the metadata for the **Vertical Datum of Data** applies to the first group of the above list. The attribute **vertical datum** on an individual feature applies to the elevation of lights and vertical clearances and must only be populated if different from the value given by **Vertical Datum of Data**.

#### Remarks:

- Value 13 (low water) for attribute **vertical datum** is only applicable to enclosed (inland) waterways; and must not be used for tidal waters.
- Height contours, going across areas having different values of vertical datum, must be split at the border of these areas.
- Meta features **Vertical Datum of Data** and **Sounding Datum** may overlap.

Distinction: Sounding Datum.

#### Inland specific Encoding Instructions:

- A) The surfaces covered by these Metadata Features must be mutually exclusive.

### 3.11 Quality of survey

**IHO Definition: QUALITY OF SURVEY.** An area within which a uniform assessment of the reliability of source survey information exists. (S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.218, November 2000).

#### **S-401 Metadata Feature: Quality of Survey (M\_SREL) (M)**

##### **Primitives: Curve, Surface**

#### Feature Associations

| S-401 Role         | Association Type                              | Associated to             | Type        | Multiplicity |
|--------------------|-----------------------------------------------|---------------------------|-------------|--------------|
| The Updated Object | <b>Updated Information</b> (see clause 25.16) | <b>Update Information</b> | Association | 0,*          |
| -                  | <b>Spatial Association</b> (see clause 25.10) | <b>Spatial Quality</b>    | Association | 0,*          |

† For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

#### 3.11.1 Survey reliability and source of bathymetric data

The survey reliability and/or details of the source surveys used in compilation may be encoded using the Meta feature **Quality of Survey**.

**Quality of Survey** can apply to bathymetry (for example, underwater rocks), non-bathymetry (for example, navigational aids) and a combination of these (for example, LIDAR survey).

#### Remarks:

- To express completeness of bathymetric data, the complex attribute **features detected** should be encoded. **features detected** indicates that a systematic method of exploring the seafloor was undertaken to detect significant features. The sub-attributes **size of features detected** and **least**

**depth of detected features measured** must not be encoded unless the sub-attribute **significant features detected** is set to *True*.

- If it is required to encode a vertical uncertainty value, it must be encoded using the complex attribute **vertical uncertainty** on an instance of the information type **Spatial Quality** (see clause 24.5), associated to the relevant feature(s) point, multipoint and curve geometry, or an instance of the Meta feature **Quality of Bathymetric Data** (see clause 3.8).
- If the attribute **measurement distance maximum** is set to 0 (zero) for the full area of the survey, the attribute **full seafloor coverage achieved** should be set to yes.
- Where populated, the value for the attribute **measurement distance minimum** must not be larger than the value populated for **measurement distance maximum**.
- **quality of horizontal measurement** on the **Quality of Survey** applies to bathymetric data situated within the area, while **quality of horizontal measurement** or **horizontal position uncertainty** on the associated spatial types qualifies the location of the **Quality of Survey** feature itself.
- The attributes **depth range maximum value** and **depth range minimum value** may be used to define the quality of individual surveys at varying depths in the water column, similar to the method used for indicating the overall quality of bathymetry using **Quality of Bathymetric Data** (see clause 3.8).

### 3.11.2 Quality of sounding

If it is required to encode the quality of sounding, it must be done using the attribute **quality of vertical measurement** on either the **Quality of Survey** or on individual geo features (for example **Sounding**).

The quality of sounding must not be encoded using **quality of vertical measurement** on the depth geo feature, unless it is different from the value of **quality of vertical measurement** encoded on **Quality of Survey** (see Table 11-1 at clause 11.3.1 and Table 13-1 at clause 13.3).

### 3.11.3 Technique of vertical measurement

If it is required to encode the technique of sounding measurement, it must be done using the attribute **technique of vertical measurement** on either **Quality of Survey** or on individual geo features (for example **Sounding**).

**technique of vertical measurement** must not be populated with multiple values to indicate the technique of sounding measurement for multiple surveys. **technique of vertical measurement** may be populated with multiple values only where the area is covered by a survey that has used multiple techniques, for example an area covered by a survey using a modern echosounder combined with a sonar or mechanical sweep system.

The technique of sounding measurement must not be encoded using **technique of vertical measurement** on the depth geo feature, unless it is different from the value of **technique of vertical measurement** encoded on an overlapping **Quality of Survey**; and the information is considered to be important to navigation.

#### Remarks:

- No remarks.

Distinction: Accuracy of Data; Quality of Bathymetric Data.

#### Inland specific Encoding Instructions:

- A) The **Quality of Survey** for soundings is only given in those areas where detailed depth information is provided. The surface feature shares the geometry with those surfaces.
- B) **Quality of vertical measurement** (QUASOU) = 1 (depth known) has to be used if the depth is known and shown via depth areas.

- C) **Quality of vertical measurement** (QUASOU) = 2 (depth unknown) is used as an feature attribute only in combination with depth surfaces (not with Metadata Feature **Quality of Survey** (M\_SREL)) for those areas in the river, which are too shallow for being surveyed by surveying boats and hence no detailed data is available (see 11.8 Unsurveyed Area).
- E) **Quality of vertical measurement** (QUASOU) = 8 (value reported (not surveyed)) must be used as an feature attribute only in combination with depth surfaces (not with Metadata Feature **Quality of Survey** (M\_SREL)) especially in cases when parts of the navigable water area are not surveyed but may be deep enough for navigation due to reports from other organisations than the waterways administration (see 11.8 **Unsurveyed Area**).
- F) **Quality of vertical measurement** (QUASOU) = 10 (maintained depth) or **Quality of vertical measurement** (QUASOU) = 11 (depth not regularly maintained) should be used as on feature attribute only in combination with **Depth Area** (DEPARE, depare) – Fairway Depth (not with Metadata Feature **Quality of Survey** (M\_SREL)) to indicate the maintenance (see 11.6 Fairway Depth / Project Depth).
- G) **Survey authority** (SURATH) has to be used to give name of the surveying authority.
- H) **Survey date range** has to be used to encode the period of the survey.
- I) Quotation: “If the attributes **uncertainty fixed** (SOUACC) and **technique of vertical measurement** (TECSOU) are required, they must be encoded on either the metadata feature **Quality of Bathymetric Data** (M\_QUAL) or on individual geo features (e.g., **Sounding** (SOUNDG)).” (see 3.8 **Quality of Bathymetric Data**)
- J) **Survey type** (SURTYP) = 2 (controlled survey) has to be used if a thorough survey has been done, usually conducted with reference to guidelines (a quality assured survey).

### 3.12 Update information

|                                                                                                                                            |                                               |                                                   |             |                     |

† For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

**fixed date range** and/or **scale minimum** are mandatory if **fixed date range** and/or **scale minimum** are populated for the associated Geo feature, and must be identical to the values populated for the associated Geo feature.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 3.12.1 Update information

In S-100 ECDIS, the existing methodology in S-57/S-52 based Inland ECDIS or ECS used to provide, on request, a visual indication to the boatmaster of information that has changed in the System Database when an IENC Update is applied will be implemented for this Edition of S-401. The following guidance, therefore, does not indicate any mandatory requirement for Data Producers or Inland ECDIS or ECS Manufacturers in regard to requirements for Inland ECDIS or ECS performance.

The meta feature **Update Information** is used by the Inland ECDIS or ECS to provide information to the boatmaster of changes that have been applied in an IENC New Edition, or to provide additional information to the boatmaster other than the visual indication when an IENC Update is applied. **Update Information** must be associated, where encoded, with features that have changed using the associations **Updated Information** (see clause 25.16) and **Update Aggregation** (see clause 25.20).

#### Remarks:

- The mandatory attribute **update number** must be used, if required, to indicate the Update number of the Update dataset that the changed information is included in, as indicated in the file extension of the Update dataset.
- The mandatory attribute **update type** must be used, if required, to indicate the type of update applicable to the feature (insertion, deletion, modification, move). Where the **Update Information** is encoded to cover an area in which numerous changes have occurred (for example in a New Edition), **update type** should be populated with value 3 (modify).
- The complex attribute **information** (see clause 2.4.6) should be used to provide a brief textual description of the changes to the associated feature as included in the Update.
- The process of moving a segment of a curve or edge of a surface feature via an IENC Update requires the two-step application of the deletion of the segment at the original position and the insertion of the new segment in the new position. Where required, in order to indicate the move of a segment by IENC Update, three **Update Information** features should be created and associated, if required, as follows:
  - An **Update Information** feature having **update type** = 2 (delete) using the geometry of the deleted segment at the original position;
  - An **Update Information** feature of type curve having **update type** = 1 (insert) associated to the inserted segment at the new position;
  - An **Update Information** feature having no geometry and **update type** = 4 (move) associated to the above “delete” and “insert” **Update Information** features using the association **Update Aggregation** (see clause 25.20).
- The association **Update Aggregation** may also be used to group several related updates, for example changes to a routing measure or aids to navigation range system. Where this is done, the **Update Information** forming the collection (container) end of the relationship should have no geometry and have **update type** = 3 (modify).
- Where the changed information is related to an information type, the **Update Information** should be associated with the features to which the information type is associated.
- The attribute **source** may be used to indicate the related paper chart Notice to Mariner’s number.

- At each New Edition of an IENC cell, **Update Information** features which are no longer relevant must be deleted; and for the next Update to an IENC cell **Update Information** features included in the previous Update dataset should be considered for deletion. Where a new Update impacts a feature that has previously been updated, any existing instance of **Update Information** associated to the feature must be deleted as part of the new Update; this must be done by deleting the existing **Update Information** from the dataset.
- The creation of **Update Information** Meta feature instances on request and the corresponding **Updated Information** and **Update Aggregation** association instances may be substantively automated in IENC production systems and associated databases, with automated population of the mandatory attributes **update number** and **update type** based on the change made to the data; and the complex attribute **fixed date range** and attribute **scale minimum** based on the attribution of the associated geo feature. The optional creation of these features and any additional information populated for **Update Information** is at the discretion of the Data Producer.

Distinction: Information Area; Caution Area.

Inland specific Encoding Instructions:

- A) If the update information should only be displayed at certain scales the attribute **scale minimum** (SCAMIN) has to be encoded.

## 4 Geo Features – Magnetic Data

### 4.1 Magnetic variation

| <b>IHO Definition: MAGNETIC VARIATION.</b> The angle between the magnetic and geographic meridians at any place, expressed in degrees east or west to indicate the direction of magnetic north from true north. Also called magnetic declination. (IHO Dictionary – S-32). |                           |                                                                                                                          |        |              |

| <b>4.1.1 Magnetic variation</b><br>Of the various magnetic data, magnetic variation is the most important element for the boatmaster. Until a world magnetic model is universally available for inclusion in Inland ECDIS or ECS, if it is                                                                                                                  |                                                 |                                                                                                                                                                                                                                                                                                    |             |                  |

required to encode magnetic variation, it must be done using the feature **Magnetic Variation**. As a minimum, updates to the magnetic variation should be supplied to coincide with changes of epoch (that is, every five years).

Remarks:

- There remains a requirement to include magnetic variation information in ENCs whilst SOLAS regulations include the requirement for a magnetic compass and deviation card. User feedback indicates that it can be difficult to access magnetic variation information in Inland ECDIS or ECS where it has been encoded using the point or curve primitive. In order to make magnetic variation information easily accessible to Inland ECDIS or ECS users, it is recommended to encode this information as Magnetic Variation features of type surface. Encoding this information using the surface primitive ensures that the user can interrogate the IENC data using the Inland ECDIS or ECS Pick Report function at any chart location to identify the value of magnetic variation at that location.
- The mandatory attribute reference year for magnetic variation must be used to populate the year value only (see clause 2.4.8 for format of date type attributes).
- Magnetic models are typically updated every five years (for example 2005, 2010... termed epochs). Magnetic variation can be calculated from computer models, or derived from charts produced by certain Hydrographic Offices or mapping authorities, which show the spatial distribution of magnetic variation values worldwide for the current epoch, by means of lines of equal magnetic variation (termed isogonals). The rate-of-change curves, which are over-printed on such charts, enable values for any point to be extrapolated for any time within the current epoch.
- Magnetic variation information in high latitudes (polar regions) is highly variable and unreliable, and as such is not normally used for navigation. It is therefore not considered to be a requirement to include magnetic variation information in IENCs covering polar waters.

Distinction:

Inland specific Encoding Instructions:

- Until a world magnetic model is universally available for inclusion in Inland ECDIS or ECS, if it is required to encode magnetic variation, it must be done using the Geo Feature **Magnetic Variation** (MAGVAR). As a minimum, updates should be supplied to coincide with changes of epoch (i.e. every five years).
- For **value of magnetic variation** (VALMAG) and **value of annual change in magnetic variation** (VALACM) a positive value, i.e. unsigned, indicates a variation (change) in an easterly direction and a negative value indicates a variation (change) in a westerly direction.

## 5 Geo Features – Natural Features

The use of Global Navigation Satellite Systems (GNSS) as an integral component of Inland ECDIS or ECS has raised questions as to the level of topographic detail that is required in IENCs to enable safe navigation using Inland ECDIS or ECS. When determining the topographic information necessary for inclusion in IENC, all operational conditions of vessels must be taken into consideration, including the potential for corruption or failure of a vessel's GNSS reception. Such a failure would require the boatmaster to navigate by fixing their position using traditional methods, necessitating a sufficient level of depiction of topographic detail in the IENC to facilitate navigation using these methods, appropriate to the Navigational Purpose of the IENC.

In addition, boatmasters will continue to use visual or radar fixing as an independent method of confirming the position of their vessel as shown on the Inland ECDIS or ECS, in order to gain a greater level of confidence in terms of their navigation.

Encoders are advised, therefore, that when determining the level of depiction of topographic detail required for IENC, this should be done in accordance with the following principles:

- The types of features charted and the distance inland to which they are shown will vary with the optimum display scale of the IENC data, type of terrain, availability of source data and, possibly, adequacy of regular navigational aids. The significance to the boatmaster must be judged by the requirements of both visual and radar navigation.
- The boatmaster sees the coast in profile; the cartographer compiles it in plan and must always be aware that the boatmaster's interest in land detail is at its greatest at the coastline and falls off rapidly inland. On a low-lying coast, even minor clues to position near the coast, for example sand dunes, hillocks, low bluffs, may be very useful on most detailed IENC datasets. On steep coasts with deep water close inshore, traffic is likely to be concentrated off projecting points of land, and the nature of each headland must be made clear, whether it has vertical cliffs, or a sloping or low profile, for example.
- Off coasts inadequately marked by navigational aids, detailed topography in the coastal belt will allow the boatmaster to clear dangers with the aid of improvised visual transits of charted topographical features.

No definite standards can be stated but the following principles should be observed:

- The density of topographic detail shown should be kept to a minimum consistent with providing navigators with all identifiable features and with a general picture of the relief as far as the probable skyline. This practice should enable landmarks to stand out from less important detail.
- Treatment of detail should vary with distance inland, for example inconspicuous features such as marshes and minor lakes and streams should be shown only when within about a mile of the coast.

Additional guidance regarding the level of depiction of topographic detail in regard to specific features is included in the following clauses.

### 5.1 Cliffs

A coast backed by rock or earth cliffs gives a good radar return and is useful for visual identification from a considerable distance off, where cliffs alternate with low lying coast along the shoreline. Where cliffs are prominent features they should be encoded on the larger optimum display scale for the IENC data; as an exception,

where cliffs predominate over extensive stretches of coastline, it may be neither feasible nor particularly useful to insert a cliff throughout. Cliff top heights are useful for calculating or estimating distance off, (for clearing inshore dangers) and should be encoded where possible.

If it is required to encode a non-coastal cliff, it must be done using the feature **Sloping Ground** (see clause 5.10) and/or using the feature **Slope Topline** (see clause 5.11), with attribute **category of slope** = 6 (cliff). For example:

**Sloping Ground** may be used at large scale to indicate the horizontal extent of the cliff.

**Slope Topline** should be used on its own to encode cliffs at small scale, or in conjunction with **Sloping Ground** to indicate the crest of the cliff when it is considered useful to know its elevation, and/or to encode a cliff on land distant from the coastline.

Remarks:

- When the cliff is coincident with the coastline, a **Coastline** feature, with attribute **category of coastline** = 1 (steep coast) should be encoded, and there should be no **Sloping Ground** or **Slope Topline** encoded.

## 5.2 Cuttings and embankments

If it is required to encode cuttings and embankments, this must be done in the same way as cliffs; using **Sloping Ground** and/or **Slope Topline** features (see clauses 5.10 and 5.11), with attribute **category of slope** = 1 (cutting) or 2 (embankment).

Remarks:

- Cuttings and embankments should be encoded only when likely to be visible from the water.

### 5.3 Coastline

IHO Definition: **COASTLINE**. The line where shore and water meet. Shoreline and coastline are generally used synonymously. (IHO Dictionary – S-32).

The official name '**Coastline**' is a synonym for the term 'shoreline' commonly used in inland navigation.

| -                     | <b>Spatial Association</b> (see clause 25.10)   | <b>Spatial Quality</b>      | Association | 0,*          |

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 5.3.1 Coastline

Natural sections of coastlines, lakeshores and riverbanks should be encoded as **Coastline**, whereas artificial sections of coastlines, lakeshores, riverbanks, canal banks and basin borders should be encoded as **Shoreline Construction** (see clause 8.6). The exception to this general rule is when a lake, river, canal, or basin is not navigable at the optimum display scale for the IENC data, in which case the boundary of the lake, river, canal, or basin must not be encoded as **Coastline** or **Shoreline Construction** as the boundary of these specific areas (**Lake, River, Canal, Dock Area, Lock Basin**) create the portrayal of the bank or shoreline.

**Coastline** and **Shoreline Construction** features form the border of the **Land Area** feature (see clause 5.4).

### 5.3.2 Natural coastline

Spatial types associated with coastlines considered to be inadequately surveyed at the optimum display scale for the IENC data should be encoded using spatial attribute **quality of horizontal measurement** = 4 (approximate).

If it is required to encode a description of the nature of the coastline, it must be done using the attributes **category of coastline** and **nature of surface**. Other surface features may be used to describe the land region adjacent to the coastline (see clause 5.11).

A steep coast may give a good radar return and is useful for visual identification from a considerable distance off, particularly where cliffs alternate with low lying coast along the shoreline.

#### Remarks:

- **Coastline** must only exist at the boundary of **Land Area** of type surface.
- **Coastline** and **Shoreline Construction** of type curve must not overlap. Similarly, **Coastline** should not share an edge with a **Shoreline Construction** of type surface (see clause 8.6) having attribute **water level effect** undefined or populated with the values 2 (always dry) or 1 (partly submerged at high water), which is covered by **Land Area**.
- If the seaward edge of an encoded saltpan area is coincident with the coastline, it should be encoded using **Coastline**, with **category of coastline** = 2 (flat coast).
- If the seaward edge of a marsh area or glacier is coincident with the coastline, the coastline should be encoded as **Coastline**, with attribute **category of coastline** = 8 (marshy shore) or 9 (glacier, seaward end). The coastline's spatial type should have the attribute **quality of horizontal measurement** = 4 (approximate). If it is required to encode the area behind the coastline, this must be done using a **Land Region** feature (for marsh – see clause 5.9)).
- If it is required to encode mangroves in the intertidal area, this should be done using an **Obstruction** feature (see clause 13.6). However, on smaller optimum display scale ENC datasets where the mangroves are required to be encoded to indicate the seaward edge of a mangrove area only as the “apparent” coastline, this must be done using **Coastline** with **category of coastline** = 7 (mangrove). The coastline's spatial type should have the attribute **quality of horizontal measurement** = 4 (approximate).
- Where the source indicates the top of a cliff is coincident with the coastline at the optimum display scale of the IENC data, a **Coastline** feature, with **category of coastline** = 1 (steep coast) should be encoded. In such cases, there should be no **Slope Topline** or **Sloping Ground** features encoded, in order to avoid clutter. If it is required to indicate that such a section of the coastline provides a good radar return, it must be done using attribute **radar conspicuous** on the **Coastline** feature. If it is required to encode a section of the coastline that is visually conspicuous, it must be done using attribute **visual prominence** on the **Coastline** feature.
- If the source indicates that the top of a coastal cliff is offset inshore from the coastline at the optimum display scale of the IENC data, a **Slope Topline** feature (see clause 5.11) and/or a **Sloping Ground** feature (see clause 5.10) may be encoded. In such cases, the **Coastline** feature should not have a value populated for **category of coastline**. If it is required to indicate that such a section of the coastline provides a good radar return, it must be done using attribute **radar conspicuous** on the **Slope Topline** and/or **Sloping Ground** feature. If it is required to encode a section of the coastline that is visually conspicuous, it must be done using attribute **visual prominence** on the **Slope Topline** and/or **Sloping Ground** feature.

Distinction: Shoreline Construction; Slope Topline; Sloping Ground.

#### Inland specific Encoding Instructions:

- EUR: The **Coastline** (COALNE) respectively shoreline should be extracted from data collected at mean water conditions, if possible.
- US: The **Coastline** (COALNE) respectively shoreline is project specific: in pool areas, project pool is used; in open water areas, shoreline should be extracted at low water conditions.

- C) When the cliff is coincident with the coastline, a **Coastline** (COALNE) feature with the attribute **category of coastline** (CATCOA) = 1 (steep coast) should be encoded and there should be no **Sloping Ground** (SLOGRD) or **Slope Topline** (SLOTOP) encoded.

## 5.4 Land area

| <b>IHO Definition:</b> LAND AREA. The solid portion of the Earth's surface, as opposed to sea, water. † Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 5.4.1 Land area

Land areas that are never covered by the sea must be encoded using the feature **Land Area**. **Land Area** features of type surface are part of the Skin of the Earth.

Rivers, canals, lakes, basins and docks, which are not navigable at the optimum display scale for the IENC data, must be encoded on top of **Land Area** features (see clause 5.4).

**Remarks:**

- If it is required to describe the natural scenery of the land, it must be done using the feature **Land Region** (see clause 5.8).
- **Land Area** is usually of type surface; it may, however, be of type point (for example islet, rock that does not cover), or of type curve (for example islet, offshore bar, isthmus).
- **Land Area** of type curve or point must not be encoded on top of **Land Area** of type surface, unless it is also covered by a **Lake, River, Dock Area, Lock Basin** or **Canal** feature of type surface.
- The limits of a **Land Area** of type surface must share the geometry of at least one of the following features:
  - o **Coastline, Shoreline Construction, Gate, Dam** of type curve;
  - o **Data Coverage, Dolphin, Exceptional Navigation Structure, Gate, Dam, River, Tunnel, Dry Dock, Canal, Lake, Lock Basin, Lock Basin Part, Dock Area, Harbour Basin, Land Area** of type surface;
  - o **Causeway, Shoreline Construction, Wreck, Obstruction, Pylon/Bridge Support** of type surface; and having attribute **water level effect** = 1 (partly submerged at high water), 2 (always dry), 4 (covers and uncovers), 5 (awash), 6 (subject to inundation or flooding), 8 (above mean water level) or 9 (below mean water level).

**5.4.2 Rocks which do not cover (islets)**

A surface feature must be encoded using:

- A **Land Area** feature of type surface (mandatory)
- **Coastline** or **Shoreline Construction** features of type curve (mandatory)
- **Land Elevation** features of type curve and/or point (optional)

A curve feature must be encoded using:

- A **Land Area** feature of type curve (mandatory)
- **Land Elevation** features of type point (optional)

A point feature must be encoded using:

- A **Land Area** feature of type point (mandatory)
- A **Land Elevation** feature of type point (optional)

Distinction: Canal; Coastline; Depth Area; Lake; Land Region; River; Seabed Area; Shoreline Construction; Vegetation.

**Inland specific Encoding Instructions:**

- A) US: Encode the land area up to the defined 1000 meter buffer zone or the distance within the radar zone for IENC charts.
- B) Curve and Point features may only be used in small-scale charts.
- C) **scale minimum** (SCAMIN) may not be encoded for type Surface, but have to be encoded for type Curve and Point (see also 2.5.9).

## 5.5 Land elevation

|                                                                                                                                                                                                                                  |                           |                                                                                                                                                                                                            |             |                     |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|---------------------|
| <b>IHO Definition: LAND ELEVATION.</b> An elevation is the vertical distance of a point or a level, on, or affixed to, the surface of the earth, measured from a specified vertical datum. (Adapted from IHO Dictionary – S-32). |                           |                                                                                                                                                                                                            |             |                     |

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 5.6.1 Height contours, spot heights

It is assumed that boatmasters will understand most methods of representation of relief with little difficulty. In general, it is assumed that Producers will choose the representation of relief most suitable to the terrain being charted and the navigational requirements. It is therefore left to national discretion to:

- omit all relief representation, except dykes and sea walls;
- omit all relief representation, except spot heights and cliffs;
- show relief by contours (and spot heights); or
- show relief by form lines (and spot heights).

Spot heights on IENC datasets should be confined to summits of hills, mountains and cliffs, particularly on datasets from which contours and form lines have been omitted; boatmasters will generally assume that heights selected for IENC are summits.

If it is required to encode a height contour or spot height, it must be done using the feature **Land Elevation**.

**Land Elevation** features must be covered by a **Land Area** feature of type surface; or a **Wreck** feature of type surface having attribute **water level effect** = 1 (partially submerged at high water) or 2 (always dry); or fall on a **Land Area** feature of type curve; or share the geometry of a **Land Area** of type point or a **Wreck** feature of type point having attribute **water level effect** = 1 (partially submerged at high water) or 2 (always dry).

Spatial types associated with approximate contours or spot heights should be encoded using the attribute **quality of horizontal measurement** = 4 (approximate).

Remarks:

- Where it would not be worthwhile to contour IENC data of smaller optimum display scale, form lines (emphasizing a few 'remarkable' hills) and/or spot heights may be used to emphasize individual features.
- Contours should reflect the nature of the topography; that is, they should not be rounded or smoothed (by generalisation) when they should really be angular.
- The contour interval must be uniform for any dataset, or series of datasets of the same or similar optimum display scale, except that the lowest contour may be a supplementary one, for example 25 metres where the basic interval is every 50 metres; or 10 metres where the basic interval is every 25 metres. Ideally the contour interval should be chosen so that not more than 10 contours are needed for the full range of height on a single dataset or particular series of datasets (for clarity and economy).
- If it is required to encode the elevation of an observation spot, benchmark or horizontal control station, it must be done using **Land Elevation**. If it is required to encode the elevation of a triangulation mark or boundary mark, it must be done using the feature **Landmark** (see clause 7.2).

Distinction: Slope Topline; Sloping Ground.

Inland specific Encoding Instructions:

---

## 5.6 River

**IHO Definition: RIVER.** A relatively large natural stream of water. (IHO Dictionary – S-32)  
This feature is used for non-navigable rivers.

|-----------------------|-------------------------------------------------|-----------------------------|-------------|--------------|
| The Updated Object    | <b>Updated Information</b> (see clause 25.16)   | <b>Update Information</b>   | Association | 0,*          |
| The Position Provider | <b>Text Association</b> (see clause 25.13).     | <b>Text Placement</b>       | Composition | 0,1          |
|                       | <b>Additional Information</b> (see clause 25.1) | <b>Nautical Information</b> | Association | 0,*          |

<sup>†</sup> Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 5.6.1 Rivers

Inland navigable waters must be compiled as fully as practicable, consistent with the optimum display scale of the IENC data. Other rivers should be compiled only in a limited way to assist in providing a general indication of the topography (except close to the coastline where they may be of direct significance to the boatmaster).

If it is required to encode a non-navigable river, stream or creek, it must be done using the feature **River**.

#### Remarks:

- If the river is navigable at the optimum display scale for the IENC data, it must be encoded using the feature **Depth Area**, **Dredged Area** (see clause 11.4) or **Unsurveyed Area**, and the riverbanks must be encoded using the feature **Coastline** or **Shoreline Construction**. The river must not be encoded as a **River** feature in this case. If it is required to encode the name of the river, it must be done using a **Sea Area/Named Water Area** feature with attribute **category of sea area** = 53 (river).
- Where the river is navigable at the optimum display scale for the IENC data, special consideration should be given to encoding features specific to the river such as minimum depths within the navigable area; overhead clearances; distances along the river; and locks and lock gates (and any associated traffic signals).
- If it is required to encode a river that is not navigable at the optimum display scale for the IENC data, it must be done using **River**, covered by a **Land Area** feature. The name of the river should be encoded using the complex attribute **feature name** on the **River** feature.
- Intermittent rivers are those that are dry most of the time, and where required must be encoded as a **River** feature with attribute **status** = 5 (periodic/intermittent).
- If it is required to encode an island in a non-navigable river encoded on **Land Area**, this must be done by encoding a "hole" in the **River** feature if the island is a surface at the optimum display scale for the IENC data, or encoding **Land Area** of type point if the island is a point at the optimum display scale for the IENC data. Encoders must not encode **Land Area** surfaces on top of **Land Area** surfaces.
- If it is required to encode an island in a non-navigable river encoded on **Unsurveyed Area**, this must be done by encoding a "hole" in both the **River** and **Unsurveyed Area** features and replacing with **Land Area** if the island is a surface at the optimum display scale for the IENC data, or encoding **Land Area** of type point if the island is a point at the optimum display scale for the IENC data. Encoders must not encode **Land Area** surfaces on top of **Unsurveyed Area** surfaces.
- Some dry riverbeds, known as wadi's, may be prominent topographic features. If it is required to encode a wadi, it should be done using a **Land Region** feature (see clause 5.8), with the name of the wadi encoded using the complex attribute **feature name**.

Distinction: Canal; Lake; Sea Area/Named Water Area; Tideway; Waterway Area.

#### Inland specific Encoding Instructions:

- Surface features should not extend into curve features as the river narrows; end where area designation ends.
- Rivers that can be used for navigation by e.g. pleasure craft should be encoded as **Depth Area** (DEPARE, depare) or **Unsurveyed Area** (UNSARE).

## 5.7 Lake

**IHO Definition:** LAKE. A large body of water entirely surrounded by land. (IHO Dictionary – S-32).

### **S-401 Geo Feature:** Lake (LAKARE) (O)

#### **Primitives:** Surface

### Feature Associations

| S-401 Role            | Association Type                                | Associated to               | Type        | Multiplicity |
|-----------------------|-------------------------------------------------|-----------------------------|-------------|--------------|
| The Updated Object    | <b>Updated Information</b> (see clause 25.16)   | <b>Update Information</b>   | Association | 0,*          |
| The Position Provider | <b>Text Association</b> (see clause 25.13).     | <b>Text Placement</b>       | Composition | 0,1          |
|                       | <b>Additional Information</b> (see clause 25.1) | <b>Nautical Information</b> | Association | 0,*          |
| -                     | <b>Spatial Association</b> (see clause 25.10)   | <b>Spatial Quality</b>      | Association | 0,*          |

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 5.10.1 Lakes

Inland navigable waters must be compiled as fully as practicable, consistent with the optimum display scale of the IENC data. Other lakes should be compiled only in a limited way to assist in providing a

general indication of the topography (except close to the coastline where they may be of direct significance to the boatmaster).

If it is required to encode a non-navigable lake, it must be done using the feature **Lake**.

Remarks:

- If the lake is navigable at the optimum display scale for the IENC data, it must be encoded using the feature **Depth Area**, **Dredged Area** (see clause 11.4) or **Unsurveyed Area**, and the lake shore must be encoded using the feature **Coastline** or **Shoreline Construction**. The lake must not be encoded as a **Lake** feature in this case. If it is required to encode the name of the lake, it must be done using a **Sea Area/Named Water Area** feature, with attribute **category of sea area** = 52 (lake).
- If it is required to encode a lake that is not navigable at the optimum display scale for the IENC data, it must be done using **Lake**, covered by a **Land Area** feature. The name of the lake should be encoded using the complex attribute **feature name** on the **Lake** feature.
- If it is required to encode an island in a non-navigable lake encoded on **Land Area**, this must be done by encoding a “hole” in the **Lake** feature if the island is a surface at the optimum display scale for the IENC data, or encoding **Land Area** of type point if the island is a point at the optimum display scale for the IENC data. Encoders must not encode **Land Area** surfaces on top of **Land Area** surfaces. If it is required to encode an island in a non-navigable lake encoded on **Unsurveyed Area**, this must be done by encoding a “hole” in both the **Lake** and **Unsurveyed Area** features and replacing with **Land Area** if the island is a surface at the optimum display scale for the IENC data, or encoding **Land Area** of type point if the island is a point at the optimum display scale for the IENC data. Encoders must not encode **Land Area** surfaces on top of **Unsurveyed Area** surfaces.
- Intermittent lakes are those that are dry most of the time, and where required must be encoded as a **Lake** feature with attribute **status** = 5 (periodic/intermittent).

Distinction: Canal; Depth Area; River; Waterway Area.

Inland specific Encoding Instructions:

---

## 5.8 Land region

**IHO Definition: LAND REGION.** An area of natural or cultivated scenery defined by its geographical characteristics and may be known by its proper name. (Adapted from S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.92, November 2000).

For IENCs: Land Areas adjacent to the waterway that are significant for navigation reference.

### **S-401 Geo Feature: Land Region (LNDRGN) (O)**

**Primitives:** Point, Curve, Surface

† At least one of the attributes **category of land region** or **feature name** must be populated.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 5.8.1 Natural sceneries

If it is required to describe the natural scenery of the land, or to give the geographic name of an area on land, it should be encoded using the feature **Land Region**.

##### Remarks:

- This feature has a use similar to that of the feature **Sea Area/Named Water Area** (see clause 9.1), but for the land.
- Sand dunes, hills and cliffs must be encoded, where required, using the feature classes **Sloping Ground** and/or **Slope Topline** (see clauses 5.10 and 5.11).
- A **Land Region** surface should be bounded, if possible, by existing curves used by other features (for example **Coastline**). If necessary, however, this surface may be bounded by other curves created to close the surface, or to describe a new surface.
- For named capes, points, peninsulas and other types of **Land Region** where there is no specific value for the attribute **category of land region**, the generic term “Cape”, “Point”, “Peninsula”, etc may be included on the complex attribute **feature name**, unless the name has been populated on an underlying **Land Area**, in which case **Land Region** should not be encoded.

- **Land Region** features of type surface may overlap.
- For additional guidance on encoding geographic names, see clause 2.5.8.

#### 5.8.1.1 Marsh

If it is required to encode a marshy area behind the coastline, it must be done using a **Land Region** feature, with attribute **category of land region** = 2 (marsh).

If the seaward edge of a marsh area is coincident with the coastline, the coastline should be encoded as a **Coastline** feature, with attribute **category of coastline** = 8 (marshy shore), and the coastline's spatial type should have the attribute **quality of horizontal measurement** = 4 (approximate) for the visible coastline.

#### 5.8.1.2 Salt pans

If it is required to encode an area on land in which seawater is evaporated, it must be done using a **Land Region** feature, with attribute **category of land region** = 15 (salt pan) covered by a **Land Area** feature (that is, the salt pan must not form a hole in the land area).

If the seaward edge of an encoded salt pan area is coincident with the coastline, this edge should also be encoded using a **Coastline** feature, with attribute **category of coastline** = 2 (flat coast).

#### 5.8.1.3 Lava flow

If it is required to encode a lava flow, it must be done using a **Land Region** feature, with attribute **category of land region** = 14 (lava flow).

If the seaward edge of an encoded lava flow area is coincident with the coastline, this edge should also be encoded using a **Coastline** feature (see clause 5.3), with attribute **nature of surface** = 11 (lava). If the source indicates that the lava flow is active, the coastline's spatial type should have the attribute **quality of horizontal measurement** = 4 (approximate).

Distinction: Land Area; Sea Area/Named Water Area; Slope Topline; Sloping Ground; Vegetation.

#### Inland specific Encoding Instructions:

- A) Land Areas adjacent to the waterway that are significant for navigation reference shall be encoded as **Land Region** (LNDRGN). Examples are landings, islands, points, bends, and any land location that should have a label readily displayed for users of the IENC.
- B) US: Use state and county abbreviations in **feature name** (OBJNAM), where applicable.
- C) US: Preferred naming will include State abbreviation on towns and cities.
- D) **Land Area** (LNDARE) has to be coded underneath **Land Region**
- E) Use **Land Region** (LNDRGN) (P) to display the name only at the location where the point was placed. Use **Land Region** (LNDRGN) (S) if display of name is desired along water area's entire expanse.
- F) US: Any important navigation notes that should always be shown on the IENC should be encoded as **Land Region** (LNDRGN) (P) on land or **Sea Area** (SEAARE) (P) features in the water.
- G) Switching yards and groups of spur lines should be coded as **Land Region** (LNDRGN) (S) features. If appropriate, code **information** (INFORM) = Switching yard. **Feature name** (OBJNAM) may be encoded with the railroad name.
- H) Use **Land Region** (LNDRGN) for boat ramps that are not functional but are common landmarks or locations for reference.  
**Feature name** (OBJNAM) shall be encoded with the name + "Boat Ramp".

## 5.9 Vegetation

**IHO Definition: VEGETATION.** Plants collectively or individually, especially those dominating a particular area or habitat. (Adapted from Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2010).

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 5.9.1 Vegetation

In most areas the vegetation cover is of negligible importance on charts with the exception of:

- Areas where trees or marsh form the apparent coastline;
- Isolated trees or clumps of trees forming landmarks;
- Where, near the coast, wooded areas alternate with areas without tree cover and so may assist in identifying headlands or other stretches of coastline.

The following features should be omitted from even the largest optimum display scale IENC data:

- Grassland, cultivated fields (including paddy fields), bushes.
- Trees along roads, fences, ditches, and scattered trees (unless landmarks).
- Woodland cover within urban areas (unless adjacent to the coast).
- Woodland cover which is the general ground cover and therefore useless for identification of position.

If it is required to encode an isolated tree used as a landmark, it must be done using a **Vegetation** feature, with attribute **category of vegetation** = 13 to 22.

#### Remarks:

- The attribute **height** is used to encode the approximate altitude of the highest point of the top of the vegetation. Where the source shows an island with the approximate height of the top of the vegetation above height datum, a **Vegetation** feature should be encoded co-incident with the **Land Area** feature of the island, with attribute **height** corresponding to the value shown on the source.
- Where it is required to encode a mangrove area or tree located in the intertidal area, this should be done using the feature **Obstruction** (see clauses 13.6 and 13.6.1.1), with attribute **category of obstruction** = 23 (mangrove). Where it is required to encode the generalised seaward edge only of a mangrove area to represent the “apparent” coastline, this must be done using the feature **Coastline** (see clause 5.3).

Distinction: Seabed Area; Seagrass; Weed/Kelp.

#### Inland specific Encoding Instructions:

- Vegetation areas and trees shall only be used on a limited level, mostly in case they are visual conspicuous to the boatmasters.
- In case trees or woods block visibility of objects, which are of relevance for navigation, they shall be encoded.
- In case large areas of reed exist and significantly mask a coastline or canal entrance, **category of vegetation** (CATVEG) = 11 (reed) shall be encoded.

## 5.10 Sloping ground

**IHO Definition: SLOPING GROUND.** An inclined surface. (S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.161, November 2000).

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 5.10.1 Sloping ground

If it is required to encode the characteristics of a prominent or visually conspicuous inclined land surface, it must be done using the feature **Sloping Ground**.

##### Remarks:

- For guidance on the encoding of cuttings and embankments, see clause 5.2.

##### 5.10.1.1 Dunes, sand hills

If it is required to encode a sand dune or sand hill, it must be done using the feature **Sloping Ground** with attribute **category of slope** = 3 (dune) or 4 (hill) and attribute **nature of surface** = 4 (sand). If these features are positioned along the coastline, a **Coastline** feature must also be encoded.

If it is required to encode the height of a dune or sand hill, a **Land Elevation** feature (see clause 5.5) must also be encoded.

Distinction: Land Elevation; Slope Topline.

Inland specific remarks:

- **Sloping Ground** (SLOGRD) is used for natural dunes or ridges, roughly paralleling the waterway, to keep flood waters within the river course.

It is also used for Cliff / Natural Rock Wall (Land rising abruptly for a considerable distance above the water or surrounding land. (IHO Dictionary, S-32, 5th Edition, 829)) and for Cuttings (excavations through high ground for a road, canal, etc.) and Embankments (artificial elevations constructed from earth, stone, etc. carrying a road, railway or similar or serving to dam water).

Inland specific Encoding Instructions:

- A) When the **Sloping Ground** (SLOGRD) is of type surface, it must have a **Land Area** (LNDARE) underneath.
- B) At large scale, the crown (the topline of the dune) may be encoded as a **Slope Topline** (SLOTOP) with **category of slope** (CATSLO) = 2 (embankment).
- C) Cliffs / Rock Walls shall be encoded using the feature **Sloping Ground** (SLOGRD) and/or **Slope Topline** (SLOTOP). **Sloping Ground** (SLOGRD) may be used at large scale to indicate the horizontal extent of the cliff. See also 5.1.  
**Slope Topline** (SLOTOP) should be used on its own to encode cliffs at small scale, or in conjunction with **Sloping Ground** (SLOGRD) to indicate the crest of the cliff when it is considered useful to know its elevation, and/or to encode a cliff on land distant from the coastline. When the cliff is coincident with the coastline, a **Coast Line** (COALNE) feature with the attribute **category of coastline** (CATCOA) = 1 (steep coast) should be encoded and there should be no **Sloping Ground** (SLOGRD) or **Slope Topline** (SLOTOP) encoded.  
 US: Use **Caution Area** (CTNARE) to buffer between waterline into depth area. **Caution Area** (CTNARE) should be a minimum of 12 m wide. Encode **Caution Area** (CTNARE) with **information text** (INFORM) = Natural Rock Wall.  
 EUR: If a rock wall is in navigable water and is a hazard to navigation, a **Caution Area** (CTNARE) shall be added.
- D) Embankments shall be encoded using the feature **Sloping Ground** (SLOGRD) and/or using the feature **Slope Topline** (SLOTOP), with the **category of slope** (CATSLO) = 2 (embankment). See also 5.2. **Sloping Ground** (SLOGRD) of type surface should be delineated at the toe of the embankment.  
**Slope Topline** (SLOTOP) should be used on its own to encode embankments at small scale and/or to encode an embankment on land distant from the shoreline.
- E) Cuttings shall be encoded using the feature **Sloping Ground** (SLOGRD) and/or **Slope Topline** (SLOTOP), with the attribute **category of slope** (CATSLO) = 1 (cutting).
- F) **Sloping Ground** (SLOGRD) may be used at a large scale to indicate the horizontal extent of the cutting or embankment.

## 5.11 Slope topline

**IHO Definition: SLOPE TOPLINE.** The upper marking of a slope, for example the ridge line or the separation line between two different gradients. (S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.160, November 2000).

### **S-401 Geo Feature: Slope Topline (SLOTOP) (O)**

#### **Primitives: Curve**

| The Position Provider | <b>Text Association</b> (see clause 25.13).     | <b>Text Placement</b>       | Composition | 0,1          |
|                       | <b>Additional Information</b> (see clause 25.1) | <b>Nautical Information</b> | Association | 0,*          |
| -                     | <b>Spatial Association</b> (see clause 25.10)   | <b>Spatial Quality</b>      | Association | 0,*          |

<sup>†</sup> Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 5.15.1 Slope topline

If it is required to encode the upper marking of a prominent or visually conspicuous land slope, it must be done using the feature **Slope Topline**.

##### Remarks:

- For guidance on the encoding of cliffs, see clause 5.1. For guidance on the encoding of cuttings and embankments, see clause 5.2.

Distinction: Coastline; Land Elevation; Sloping Ground.

##### Inland specific Encoding Instructions:

- The crown (the topline of a dune) may be encoded as a **Slope Topline** (SLOTOP) with **category of slope** (CATSLO) = 2 (embankment).
- Cliffs / Rock Walls shall be encoded using the feature **Sloping Ground** (SLOGRD) and/or **Slope Topline** (SLOTOP). See also 5.1.

- C) **Slope Topline** (SLOTOP) should be used on its own to encode cliffs at small scale, or in conjunction with **Sloping Ground** (SLOGRD) to indicate the crest of the cliff when it is considered useful to know its elevation, and/or to encode a cliff on land distant from the coastline.
- D) When the cliff is coincident with the coastline, a **Coastline** (COALNE) feature with the attribute **category of coastline** (CATCOA) = 1 (steep coast) should be encoded and there should be no **Sloping Ground** (SLOGRD) or **Slope Topline** (SLOTOP) encoded.
- E) Cuttings shall be encoded using the feature **Sloping Ground** (SLOGRD) and/or **Slope Topline** (SLOTOP), with the attribute **category of slope** (CATSLO) = 1 (cutting). See also 5.2.
- F) Embankments shall be encoded using the feature **Sloping Ground** (SLOGRD) and/or using the feature **Slope Topline** (SLOTOP), with the **category of slope** (CATSLO) = 2 (embankment). See also 5.2.
- G) **Slope Topline** (SLOTOP) should be used on its own to encode embankments at small scale and/or to encode an embankment on land distant from the shoreline.
- H) The crown of a dyke (the topline of the dyke) may be encoded as a **Slope Topline** (SLOTOP) with **category of slope** (CATSLO) = 2 (embankment) at large scale.

## 5.12 Tideway

**IHO Definition: TIDEWAY.** A channel through which a tidal current runs. (IHO Dictionary – S-32). A natural water course in intertidal areas where water flows during the ebb or flood can also be encoded as **Tideway** (TIDEWY) in IENCs.

### **S-401 Geo Feature: Tideway (TIDEWY) (O)**

#### **Primitives: Curve, Surface**

|                       | <b>Additional Information</b> (see clause 25.1) | <b>Nautical Information</b> | Association | 0,*          |
| -                     | <b>Spatial Association</b> (see clause 25.10)   | <b>Spatial Quality</b>      | Association | 0,*          |

<sup>†</sup> Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 5.12.1 Tideways

If it is required to encode a natural watercourse in intertidal areas, for example formed by the outflow of a stream or by tidal action, it must be done using the feature **Tideway**.

Remarks:

- No remarks.

Distinction: Canal; River; Sea Area/Named Water Area; Waterway Area.

Inland specific Encoding Instructions:

- A) This feature must be on top of features of Group 1 (**Depth Area** (DEPARE, depare), **Dredged Area** (DRGARE) or **Unsurveyed Area** (UNSARE)).

## 6 Geo Features – Cultural Features

### 6.1 Built-up area

**IHO Definition: BUILT-UP AREA.** An area of land or construction over the water containing a concentration of buildings and/or other structures. (Adapted from Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2010).

#### **S-401 Geo Feature: Built-Up Area (BUAARE) (O)**

**Primitives:** Point, Surface

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 6.1.1 Built-up areas

When representing built-up areas, the aim of the compiler must be to create the correct impression of the extent of the built-up area.

If it is required to encode a built-up area, it must be done using the feature **Built-Up Area**.

##### Remarks:

- A built-up area crossed by curve features (for example roads, streets, railways) should not be divided into multiple features, unless separate sections of the built-up area have at least one different attribute value.
- However, for presentation purposes, a built-up area of type surface crossed by a river or canal of type surface must be divided into several features, with the built-up area features not overlapping the river or canal feature. A built-up area of type surface should not overlap a lake, dock or lock basin feature of type surface.
- Several buildings or built-up areas may be referred to by the same settlement, village or town name on the source. In such cases, the individual buildings or built-up areas should be encoded as separate unnamed features, using the features **Building** or **Built-Up Area**, and additionally, an **Administration Area** feature (see clause 16.9) covering the whole named area should be created with the name encoded using the attribute **feature name**. The encoded **Administration Area** feature should also have the attribute **jurisdiction** = 3 (national sub-division).
- **Built-Up Area** should be covered by **Land Area** features of type surface, or be coincident with **Land Area** features of type point.
- Where the source indicates that a built-up area extends into navigable water (over **Depth Area** or **Unsurveyed Area** feature(s)), the **Built-Up Area** should be extended over the water area and the Boolean attribute **in the water** must be set to *True* to indicate that the feature is to be included in the Inland ECDIS or ECS Base Display. The actual coastline should be encoded as **coastline**, having no value populated for **category of coastline**. There is no requirement to split the **Built-Up Area** into two separate features where it crosses the coastline; or to encode the “apparent” coastline (seaward edge of the built-up[ area). Underlying bathymetry (depth contours, soundings) may be encoded as required. Exceptionally, encoders may extend the underlying **Land Area** and **Coastline**

features seaward to the “apparent” coastline. This encoding should be considered for generalization purposes on smaller scale IENCs. Where the built-up area extends over navigable water it is not required to encode any supporting structures (for example piles, stilts).

- For encoding individual buildings over navigable water, see clause 6.2.1.

Distinction: Building; Landmark; Railway; Road.

Inland specific Encoding Instructions:

- A) EUR: Outline of **Built-up Areas** (BUAARE) using surface feature should be real built-up areas; only in case no detailed data is available (e.g., from flight surveys or satellite pictures) the political bounds can be used.
- B) US: Outline of **Built-up Areas** (BUAARE) should be the political bounds.
- C) **Category of built-up area** (CATBUA) may be encoded according to the following definitions based on inhabitants:  
 Urban area (more than 100.000)  
 City (20.000 – 100.000)  
 Town (5.000 – 20.000)  
 Village (100 - 5000)  
 Settlement (few houses/farms)
- D) **Built-up Areas** (BUAARE) should be represented as point feature for towns and small communities where the limits are not known. Points should be oriented on the highest buildings (e.g., church towers) or the town centres.
- E) Built-up areas that use the shoreline as a limit must share the same geometry.
- F) US: Use name and state abbreviation, e.g., Westport, MS for **feature name** (OBJNAM).
- G) EUR: If the ISRS Location Code is available, it has to be encoded (refer to 2.4.13) If a MRN or RIS-ID is available, the attribute **interoperability identifier** must be encoded (refer to **Fehler! Verweisquelle konnte nicht gefunden werden.**).
- H) Collect areas of buildings that are not individually navigationally significant as **Built-up Areas** (BUAARE) by collecting a surface around the outer edges of the outermost buildings or street patterns.
- I) It is recommended that minimal Railway (RAILWY) features be collected in a **Built-up Area** (BUAARE).
- J) In **Built-up Areas** (BUAARE), with exception to roads providing access to the waterfront, **Roadways** (ROADWY) should be restricted to a set of routes representative of the urban layout.

## 6.2 Building

**IHO Definition: BUILDING.** A free-standing self-supporting construction that is roofed, usually walled, and is intended for human occupancy (for example: a place of work or recreation) and/or habitation. (Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2010).  
For IENCs: Buildings with a special function, which may be of interest for the boatmaster.

### **S-401 Geo Feature: Building (BUISGL) (O)**

† The sub-attribute **colour pattern** is mandatory for buildings that have more than one value populated for the sub-attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 6.2.1 Buildings

Waterfront, landmark and some public buildings should be encoded precisely and individually on the larger optimum display scale IENC data. When representing buildings generally, forming urban and suburban areas, villages, and other built-up areas, the aim of the compiler must be to create the correct impression of the extent of the built-up area and the density of the buildings.

Within built-up areas, only waterfront, landmark, and certain public buildings of interest should be encoded individually.

Scattered buildings of no individual importance must be omitted when more than about 2 kilometres inland. Nearer the shore they may be generalised by encoding a few representative buildings, sufficient to give the correct impression of building density.

Public buildings, with the possible exception of Post Offices and Hospitals, are charted mainly as visual features or points of reference ashore, not for their interest for particular functions. Except where they could be useful landmarks for navigation, they should be encoded only on largest optimum display scale IENC data.

Buildings constructed as places of worship often form significant landmarks; their size and structure incorporating towers, spires, cupolas, etc often render them conspicuous. These buildings when known to be prominent or conspicuous should be encoded up to several miles inland, with sufficient information to enable them to be easily identified. When the optimum display scale for the IENC data permits, the building should be encoded as a surface feature with attention being drawn to any significant features (landmarks).

If it is required to encode a building (other than a landmark, tank, silo or roofed structure erected or extending over navigable water), it must be done using the feature **Building**.

#### Remarks:

- For landmarks, see clause 7.2; for silos, tanks and water towers, see clause 7.3. For common encoding combinations, see clause 7.1. For roofed structures such as boathouses erected or extending over navigable water to provide protection for a vessel or its cargo, see clause 8.7.
- 
- The feature association **Structure/Equipment** (see clause 25.12) must only be used with **Building** features if the main purpose of the building is to act as an aid to navigation (for example a lighthouse).
- A ruined building should be encoded in the same way as the feature in good condition, but with attribute **condition** = 2 (ruined).
- For an encoded **Building** feature located in navigable water, the Boolean attribute **in the water** must be set to *True* to indicate that the feature is to be included in the Inland ECDIS or ECS Base Display. Where such structures are located in the water it is not required to encode any supporting structures (for example piles, stilts).
- If it is required to encode vertical and/or horizontal clearances and any other information relevant for allowing vessels to enter or berth beneath/within the structure, this must be done by encoding the structure using the feature **Structure Over Navigable Water** (see clause 8.7).
- When a building is shown as a surface, indicating its true shape, and it is required to encode a prominent feature such as a tower or spire that is part of the structure, two features must be created (see Figure 6-1 below):

- a **Building** feature of type surface for the main building,
- a **Landmark** feature of type point for the prominent feature.

**Figure 6-1 – Landmarks**

- If available and considered important for route planning and/or monitoring, the vertical uncertainty associated with encoded vertical clearance values should also be encoded.

### 6.2.2 Harbour offices

If it is required to encode a harbour office, it must be done using a **Building** feature, with the attribute **function** taking at least one of the values:

- 2 - harbour-masters office
- 3 - customs office
- 4 - health office
- 11 - pilot office

### 6.2.3 Transit sheds and warehouses

If it is required to encode a transit shed or warehouse, it must be done using a **Building** feature, with attributes **function** = 15 (transit shed/warehouse), and if it is required, **feature name (name)** = name or number of the shed.

Distinction: Built-Up Area; Coast Guard Station; Landmark; Rescue Station; Silo/Tank, Structure Over Navigable Water.

#### Inland specific distinctions:

- A) Fortified structures shall be encoded as **Fortified Structures** (FORSTC), E.3.3, if they can be seen from the water.
- B) Buildings that are visible from the water and that may be used as landmarks shall be collected as **Landmark** (LNDMRK) if possible.
- C) Buildings that can be encoded as **Harbour Facility** (HRBFAC, hrbfac) should not be encoded as **Building** (BUISGL).

#### Inland specific Encoding Instructions:

- A) Only buildings with a special function, which may be of interest for the skipper, should be encoded as **Building** (BUISGL).
- B) Collect areas of buildings that are not individually navigationally significant as **Built-up Areas** (BUAARE) by collecting a surface around the outer edges of the outermost buildings or street patterns.

- C) Buildings or structures with specialized functions must be attributed with the appropriate enumeration of the attribute **function** (FUNCTN).
- D) Buildings that extend into water should be encoded as Dock/Wharf (**Shoreline Construction** (SLCONS, slcons)) with appropriate enumeration of the attribute **category of shoreline construction** (CATSLC). Then the building should be placed on that dock.

### 6.3 Airport/airfield

**IHO Definition: AIRPORT/AIRFIELD.** A defined area on land (including any buildings, installations and equipment) intended to be used either wholly or in part for the arrival, departure and surface movement of aircraft. (Adapted from Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2010).

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 6.3.1 Airfields

Airfields (or airports) within a few miles of the coast must be charted on larger and medium optimum display scale IENC data; they are significant to coastal navigation because of the many visual and audible features associated with them and the related air traffic.

For IENC data at larger optimum display scales, an airport should be encoded using a combination of the following features: **Airport/Airfield** (surface), **Runway** (surface or curve), **Building** (surface or point) and **Landmark** (surface or point). At least one **Airport/Airfield** or **Runway** must be in this set of features.

For IENC data at smaller optimum display scales, an airport should be encoded as an **Airport/Airfield** of type point.

#### Remarks:

- If individual buildings are visually conspicuous, they must be encoded as separate features.
- If it is required to encode the control tower, it must be done using a **Landmark** feature, with attributes **function** = 39 (control) and **category of landmark** = 17 (tower). If it is required to encode other buildings, this must be done using the feature **Building**.
- If it is required to encode a seaplane landing area, it must be done using the feature **Seaplane Landing Area** (see clause 16.6).
- For navigational aids associated with air navigation, and air obstruction lights, see clauses related to navigational aids.

Distinction: Helipad, Runway; Seaplane Landing Area.

#### Inland specific Encoding Instructions:

- Code outline of runways. Include taxiways and tarmacs, if the information is available.
- Coding as a point is subject to data availability or subject to the scale of the chart.
- Runways where lights can be seen from passing vessels shall be encoded.

## 6.4 Runway

**IHO Definition: RUNWAY.** A defined area, on a land aerodrome, prepared for the landing and take-off run of aircraft. (Adapted from IHO Dictionary – S-32).

### **S-401 Geo Feature: Runway (RUNWAY) (O)**

#### **Primitives: Point, Curve, Surface**

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 6.4.1 Airfields

Airfields (or airports) within a few miles of the coast must be encoded on large and medium optimum display scale IENC data; they are significant to coastal navigation because of the many visual and audible features associated with them and the related air traffic.

For larger optimum display scale IENC data, an airport should be encoded using a combination of the following features: **Airport/Airfield** (surface), **Runway** (surface or curve), **Building** (surface or point) and **Landmark** (surface or point). At least one **Airport/Airfield** or **Runway** must be in this set of features.

##### Remarks:

- Two or more crossing runways may be encoded as one surface.
- If it is required to encode a seaplane landing area, it must be done using the feature **Seaplane Landing Area** (see clause 16.6).
- For navigational aids associated with air navigation, and air obstruction lights, see clauses related to navigational aids.

Distinction: Airport/Airfield; Helipad; Seaplane Landing Area.

##### Inland specific Encoding Instructions:

- Coding as point or curve is subject to data availability or subject to the scale of the chart.
- Runways where lights can be seen from passing vessels should be encoded.

## 6.5 Helipad

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### Helipads

If it is required to encode a helipad, it must be done using the feature **Helipad**.

#### Remarks:

- Heliports must be encoded, where required, using the feature **Airport/Airfield** (see clause 6.3). Where a heliport has been encoded, there is no requirement to indicate the individual helipads using **Helipad**.
- If it is required to encode an area where helicopters may st down on water, it must be done using the feature **Seaplane Landing Area** (see clause 16.6).
- Where a **Helipad** feature has been encoded as part of an offshore platform, it must be associated to the **Offshore Platform** feature (see clause 14.1) using the association **Structure/Equipment** (see clause 25.12).
- For navigational aids associated with air navigation, and air obstruction lights, see clauses related to navigational aids.

Distinction: Airport/Airfield; Runway; Seaplane Landing Area.

#### Inland specific Encoding Instructions:

- A) Coding as point or curve is subject to data availability or subject to the scale of the chart.
- B) Helipads where lights can be seen from passing vessels should be encoded.

## 6.6 Bridge

**IHO Definition: BRIDGE.** A structure erected over a depression or an obstacle such as a body of water, railroad, etc., to provide a roadway for vehicles or pedestrians. (IHO Dictionary – S-32).

† For bridges encoded over navigable water, the attribute **opening bridge** is mandatory.

The sub-attribute **colour pattern** is mandatory for bridges that have more than one value populated for the sub-attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 6.6.1 Bridges

If it is required to encode a bridge, it should be done using the feature **Bridge**. Bridges may be encoded over water that is navigable or non-navigable at the optimum display scale of the IENC data. Where the bridge is encoded over navigable water, associated features such as spans, pylons and pontoons of the bridge must be associated with the **Bridge** feature using the association **Bridge Aggregation** (see clause 25.3) (that is, the **Bridge** feature has geometry of type curve or surface, or has no

geometry). Where the bridge is encoded over non-navigable water, then it must be encoded, where required, using a **Bridge** feature having no component features (that is, the **Bridge** feature has geometry of type curve or surface); or as a **Landmark** feature (see clause 7.2) if the bridge has geometry of type point.

The value of the vertical clearance between (high) water level and any fixed overhead obstruction must always be given, where known, on the largest optimum display scale IENC data intended for navigation under the bridge, and for detailed passage planning. The datum above which clearances are given must be a high water level, preferably Highest Astronomical Tide (HAT), where the tide is appreciable. For bridges over navigable water, the value for the vertical clearance(s) must be encoded using the features **Span Fixed** or **Span Opening** (see clauses 6.7 and 6.8), with the clearance(s) populated using the complex attributes **vertical clearance fixed**, **vertical clearance closed** and/or **vertical clearance open**, and sub-attributes populated relevant to the span.

#### Remarks:

- If it is required to encode the name of a bridge over navigable water, the **Bridge** should be encoded using geometry of type curve or surface, associated with all relevant components of the bridge using the association **Bridge Aggregation**. The extent of the geometry of the **Bridge** should utilise the geometry of all the components of the bridge so as to cover its full extent.
- If it is required to encode the extent of an unnamed bridge over navigable water, this may be done using a **Bridge** feature having no geometry, associated with all relevant components of the bridge using the association **Bridge Aggregation**.
- Water under a bridge must be encoded using the features **Depth Area**, **Dredged Area** or **Unsurveyed Area** (and appropriate **Depth Contour** and **Sounding** features) if the waterway is navigable at the optimum display scale for the IENC data, or using the feature **Land Area** if the waterway is not navigable at the optimum display scale for the IENC data.
- When there is a fixed vertical clearance, closed vertical clearance, or open vertical clearance given for a bridge, it should be applied only to the portion of the bridge to which the clearance refers, using the features **Span Fixed** or **Span Opening** (see clauses 6.7 and 6.8). All encoded bridge spans must be associated with the **Bridge** feature using the association **Bridge Aggregation** (see clause 25.3). See examples in the Figures below. If there are no vertical clearances given for a bridge and it is over water that is navigable at the optimum display scale of the IENC data, a single **Span Fixed** or **Span Opening** feature must be encoded covering the area of the bridge, having mandatory vertical clearance attributes populated with an empty (null) value.
- The attribute **height** is used, where required, to encode the height of the highest point on the bridge structure (see clause 2.5.7).
- If it is required to encode a bridge for which part or the entire span is moved aside or backwards, it must be done using a **Bridge** feature, with attributes **opening bridge** = *True* and **category of opening bridge** = 7 (drawbridge).
- If it is required to encode a pontoon bridge where a pontoon section may be temporarily removed or rotated so as to allow passage of vessels, this must be done using a **Bridge** feature, with attributes **bridge construction** = 3 (pontoon bridge), **opening bridge** = *True* and **category of opening bridge** = 3 (swing bridge) or 7 (draw bridge).
- If it is required to encode a distance mark that is included on or associated with a bridge, this must be done using the feature **Distance Mark** (see clause 8.10).
- In navigable water, bridge supports must be encoded, where possible, using a **Pylon/Bridge Support** feature (see clause 6.12), with attribute **category of pylon** = 4 (bridge/pylon tower) or 5 (bridge pier) or if the bridge is a pontoon bridge as **Pontoon** features (see clause 8.19).
- It is not mandatory to encode roads or railways on bridges.

### 6.6.2 Examples of Encoding Common Bridge Types

**PONTOON BRIDGE (Opening)**

**Bridge** feature (surface): Geometry of all components  
 bridge construction = 3 (pontoon bridge)  
 category of opening bridge = 3 (swing bridge)  
 feature name = *Koningin Emmabrug*  
 opening bridge = *True*

*The Component(s)*  
 (associated by Bridge Aggregation)

**Span Opening**

vertical clearance open  
 vertical clearance unlimited = *True*  
 vertical clearance closed  
 vertical clearance value = *0.0*  
 information  
 text = *Span pivots at western end*

**Span Fixed**

vertical clearance fixed  
 vertical clearance value = *0.0*

Pontoon

**Figure 6-3 – Pontoon bridge (opening) – Example**

**PONTOON BRIDGE (Fixed)**

**Bridge** feature (surface): Geometry of all components  
 bridge construction = 3 (pontoon bridge)  
 feature name = *Grolsch Bridge*  
 opening bridge = *False*

*The Component(s)*  
 (associated by Bridge Aggregation)

Pontoon

**Span Fixed**

vertical clearance fixed  
 vertical clearance value = *0.0*

**Figure 6-4 – Pontoon bridge (fixed) – Example**

Inland specific Encoding Instructions:

A) All bridge types:

- i) Bridge approaches (over the bankline) should be encoded.
- ii) Roads and railways on bridges shall not be encoded.
- iii) Place **Light All Around, Sectored Lights or Light Air Obstruction** (LIGHTS) at appropriate position on bridge features and piers bounding navigable channel.
- iv) The ISRS Location Code of a bridge is assigned to each single span feature of the entire bridge (refer to 2.4.13). If a MRN or RIS-ID is available, the attribute **interoperability identifier** must be encoded (refer to **Fehler! Verweisquelle konnte nicht gefunden werden.**).
- v) **category of bridge** (CATBRG) has to be encoded for the **Bridge** feature if all spans have the same category. If they have different categories the attribute has to be only encoded for the individual spans.
- vi) For notice marks on bridges see clause 20.17.
- vii) Use **pictorial representation** (PICREP).

US: **pictorial representation (PICREP)** is mandatory

EUR: **pictorial representation (PICREP)** is optional

B) Bridges with opening spans:

- i) The portions of the bridge that approach the span opening from either shore are to be encoded as span fixed (separate features). Only that portion of the bridge that is actually movable is to be encoded as a span opening.

C) Swing Bridge

- i) US & EUR: Add a **Caution Area (CTNARE)** feature (**information text (INFORM)** = Swing Area) around the swing area that is showing the actual swing area of the swinging bridge span.

## 6.7 Span fixed

**IHO Definition: SPAN FIXED.** A fixed component of the deck of a bridge spanning successive bridge piers. (Adapted from Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2013).

### **S-401 Geo Feature: Span Fixed (bridge) (M)**

<sup>†</sup> For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

#### 6.7.1 Span fixed

If it is required to encode the clearance characteristics (vertical or horizontal) for any fixed part of a bridge between piers or supports, it must be done using the feature **Span Fixed**, which must be associated with the feature **Bridge** (see clause 6.6) using the association **Bridge Aggregation** (see clause 25.3). See clause 6.6 for examples of **Span Fixed** features aggregated to **Bridge**.

The value of the vertical clearance between (high) water level and any fixed overhead obstruction must always be given, where known, on the largest optimum display scale IENC data intended for

navigation under the overhead obstruction, and for detailed passage planning. The datum above which clearances are given must be a high water level, preferably Highest Astronomical Tide (HAT), where the tide is appreciable. Clearances must be populated using the complex attribute **vertical clearance fixed** and sub-attributes populated relevant to the feature.

Remarks:

- **Span Fixed** features should only be encoded if the span is entirely or partly over navigable water at the optimum display scale for the IENC data.
- Where the optimum display scale of the IENC data is such that individual spans on a fixed bridge over navigable water cannot be indicated, the entire bridge should be covered by a single **Span Fixed** feature, having attributes populated according to the most navigationally important span.
- Value 13 (low water) for attribute **vertical datum** is only applicable to enclosed (inland) waterways; and must not be used to indicate the reference datum for vertical clearances in tidal waters.
- Where encoded, an associated instance of the cartographic feature **Text Placement** (see clause 23.1) relates to the positioning of the vertical and/or horizontal clearances for the span, where encoded. If available and considered important for route planning and/or monitoring, the vertical uncertainty associated with encoded vertical clearance values should also be encoded.

Distinction: Bridge; Cable Overhead; Conveyor; Pipeline Overhead; Span Opening.

Inland specific Encoding Instructions:

- A) All bridge types:
- i) Bridge approaches (over the bankline) should be encoded.
  - ii) The ISRS Location Code of a bridge is assigned to each single span feature of the entire bridge (refer to 2.4.13). If a MRN or RIS-ID is available, the attribute **interoperability identifier** must be encoded (refer to **Fehler! Verweisquelle konnte nicht gefunden werden.**).
  - iii) Use **vertical datum** (VERDAT) only if vertical datum differs:
    - from DSPM VDAT subfield and
    - from Metadata feature **Vertical Datum of Data** (m\_vdat) attribute.
  - iv) If there is no vertical clearance indicator at a bridge, but there is a gauge which can be used to calculate the vertical clearance of the bridge depending on the water level, it should be encoded in accordance with clause 22.15.
  - v) EUR: If there is a gauge which can be used to calculate the vertical clearance of the bridge, the ISRS Location Code of the gauge shall be encoded in the attribute **reference gauge** (refgag).
  - vi) Use **name of vertical river datum reference level** (vcrlev) and **vertical river datum reference level value** (vcrval) if the local value and name of vertical river datum reference level (design waterlevel ) is known.
  - vii) **bridge construction** (CATBRG) has to be encoded for the **Bridge** feature if all spans have the same category. If they have different categories the attribute has to be only encoded for the individual spans.
  - viii) **Vertical clearance value** (VERCLR), **horizontal clearance value** (HORCLR), **waterway distance** (WTWDIS) and **distance unit of measurement** must be encoded for spans over navigable water. **Vertical clearance value** (VERCLR) should not be encoded for spans over non-navigable water.
  - ix) US: If separate spans are required, each span's **information** (INFORM) should indicate whether it is the "Primary Navigation Span", "Secondary Navigation Span", or "Not to be used for Navigation."
- B) Bridge with Bridge Arches
- i) The following instructions are only necessary if the available space according to the beam and air-draft of the vessel shall be indicated.

- This is only possible if the arch of the span can be separated into different single pieces with known vertical clearances or if the arc is mathematically known.
- Create several span fixed features with **bridge construction** (CATBRG) = 1 (arch) for one bridge arch.
- The number of the span fixed features depends on the resolution of the different vertical clearances which shall be provided. The width of the element with the biggest vertical clearance should not be less than the typical width of vessels (12 m for European waterways of CEMT class IVa and above).
- The areas must not overlap.
- All of the span fixed features of one arch which are situated within the allowed passage must be aggregated by a **Bridge Arch Association**.

ii) **Bridge Arch Association** must NOT be included in the **Bridge Aggregation**.

## 6.8 Span opening

**IHO Definition: SPAN OPENING.** An opening component of the deck of a bridge spanning successive bridge piers. (Adapted from Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2013).

† For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

The sub-attribute **vertical clearance value** for the complex attribute **vertical clearance open** is mandatory if the sub-attribute **vertical clearance unlimited** is set to *False*.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

### 6.8.1 Span opening

If it is required to encode the clearance characteristics (vertical or horizontal) for an opening part of a bridge between piers or supports, it must be done using the feature **Span Opening**, which must be associated with the feature **Bridge** (see clause 6.6) using the association **Bridge Aggregation** (see clause 25.3). See clause 6.6 for examples of **Span Opening** features used in conjunction with **Bridge** features.

The value of the vertical clearance between (high) water level and any opening overhead obstruction must always be given, where known, on the largest optimum display scale IENC data intended for navigation under the overhead obstruction, and for detailed passage planning. The datum above which clearances are given must be a high water level, preferably Highest Astronomical Tide (HAT), where the tide is appreciable. Clearances must be populated using the complex attributes **vertical clearance closed** and **vertical clearance open** for the span and sub-attributes populated relevant to the feature.

#### Remarks:

- **Span Opening** features should only be encoded if the span is entirely or partly over navigable water at the optimum display scale for the IENC data.
- Where the optimum display scale of the IENC data is such that individual spans over navigable water cannot be indicated, the entire bridge should be covered by a single **Span Opening** feature, having attributes populated according to the opening span.
- The complex attributes **vertical clearance closed** and **vertical clearance open** must be encoded for both the opening (vertical open) and closed (vertical closed) clearance values. Where the open vertical clearance is unlimited, the Boolean sub-attribute **vertical clearance unlimited** must be set to *True*.
- Where it is required to encode time schedule information relating to the opening and closing times for the span, including any scheduled closure times or amended schedules for festivals or national holidays, this should be done using an associated instance of the information types **Service Hours** (see clause 24.2) and/or **Non-Standard Working Day** (see clause 24.3).
- Value 13 (low water) for attribute **vertical datum** is only applicable to enclosed (inland) waterways; and must not be used to indicate the reference datum for vertical clearances in tidal waters.
- Where encoded, an associated instance of the cartographic feature **Text Placement** (see clause 23.1) relates to the positioning of the vertical and/or horizontal clearances for the span, where encoded. If available and considered important for route planning and/or monitoring, the vertical uncertainty associated with encoded vertical clearance values should also be encoded.

Distinction: Bridge; Cable Overhead; Conveyor; Pipeline Overhead; Span Fixed.

#### Inland specific Encoding Instructions:

- A) All bridge types:
  - i) Bridge approaches (over the bankline) should be encoded.

- ii) The ISRS Location Code of a bridge is assigned to each single span feature of the entire bridge (refer to 2.4.13). If a MRN or RIS-ID is available, the attribute **interoperability identifier** must be encoded (refer to **Fehler! Verweisquelle konnte nicht gefunden werden.**).
- iii) Use **vertical datum** (VERDAT) only if vertical datum differs:
  - from DSPM VDAT subfield and
  - from Metadata feature **Vertical Datum of Data** (m\_vdat) attribute.
- iv) For time schedule (general) see clause 24.6.
- v) If there is no vertical clearance indicator at a bridge, but there is a gauge which can be used to calculate the vertical clearance of the bridge depending on the water level, it should be encoded in accordance with clause 22.15.
- vi) EUR: If there is a gauge which can be used to calculate the vertical clearance of the bridge, the ISRS Location Code of the gauge shall be encoded in the attribute **reference gauge** (refgag).
- vii) Use **name of vertical river datum reference level** (vcrlev) and **vertical river datum reference level value** (vcrval) if the local value and name of vertical river datum reference level (design waterlevel ) is known.
- viii) **bridge construction** (CATBRG) and **category of opening bridge** (CATBRG) have to be encoded for the **Bridge** feature if all spans have the same type. If they have different types the attribute has to be only encoded for the individual spans.
- ix) **Horizontal clearance value** (HORCLR), **vertical clearance closed** (VERCCL) and/or **vertical clearance open** (VERCOP), **waterway distance** (WTWDIS) and **distance unit of measurement** must be encoded for spans over navigable water. **Vertical clearance value** (VERCLR) should not be encoded for spans over non-navigable water.

## 6.9 Conveyor

**IHO Definition: CONVEYOR.** A mechanical device for conveying bulk material or people using an endless moving belt or series of rollers. (Adapted from Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2010).

† The attribute **colour pattern** is mandatory for conveyors that have more than one value populated for the attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

For conveyors encoded over navigable water, the attribute **vertical clearance fixed** is mandatory.

### 6.9.1 Conveyors

If it is required to encode a conveyor, it must be done using the feature **Conveyor**.

The value of the vertical clearance between (high) water level and any fixed overhead obstruction must always be given, where known, on the largest optimum display scale IENC data intended for navigation under the obstruction, and for detailed passage planning. The datum above which clearances are given must be a high water level, preferably Highest Astronomical Tide (HAT), where the tide is appreciable. The value for the vertical clearance must be encoded for conveyors located over navigable water using the complex attribute **vertical clearance fixed**, and sub-attributes populated relevant to the feature.

#### Remarks:

- If it is required to encode an overhead cable car, it must be done using a **Conveyor** feature, with attribute **category of conveyor** = 1 (aerial cableway).
- In navigable water, conveyor supports must be encoded, where possible, using a **Pylon/Bridge Support** feature (see clause 6.12), with attribute **category of pylon** = 3 (aerial cableway pylon).

- Value 13 (low water) for attribute **vertical datum** is only applicable to enclosed (inland) waterways; and must not be used to indicate the reference datum for vertical clearances in tidal waters.
- If available and considered important for route planning and/or monitoring, the vertical uncertainty associated with encoded vertical clearance values should also be encoded.

Distinction: Cable Overhead; Crane; Pylon/Bridge Support.

Inland specific Encoding Instructions:

- A) Place curve feature from land-based facility to fixed structure in water at which product loads or offloads.
- B) If a conveyor extends over navigable water it has to be encoded.
- C) Use **name of vertical river datum reference level (VCRLEV)** and **vertical river datum reference level value (VCRVAL)** if the local value and name of vertical river datum reference level (design waterlevel ) is known.
- D) Aerial cableway
  - i) If an aerial cableway extends over navigable water it has to be encoded.
  - ii) For an aerial cableway for the transport of people the attribute **product** (PRODC) should not be encoded. If the **feature name** (OBJNAM) doesn't show that it is an aerial cableway for the transport of people, the information can be encoded in the attribute **information text** (INFORM).
  - iii) Cable supports (**Pylon/Bridge Support** (PYLONS), **category of pylon** (CATPYL) = 3) closest to the landside of the bank line and those within the water must be coded.
  - iv) The **vertical clearance value** (VERCLR) shall be provided in metres and indicate the vertical distance between the lowest car or bucket (over the navigable part of the waterway) and a defined high water level (e.g. highest shipping height of water) if available.
  - v) If there is no vertical clearance indicator at the cableway, but there is a gauge which can be used to calculate the vertical clearance of the cableway depending on the water level, it should be encoded in accordance with 22.15.
  - vi) EUR: If there is a gauge which can be used to calculate the vertical clearance of the cableway, the ISRS location code of the gauge shall be encoded in the attribute **reference gauge** (refgag).
  - vii) Use **name of vertical river datum reference level** (vcrlev) and **vertical river datum reference level value** (vcrval) if the local value and name of vertical river datum reference level (design waterlevel ) is known.

## 6.10 Cable overhead

**IHO Definition: OVERHEAD CABLE.** A single continuous rope-like bundle consisting of multiple strands of fiber, plastic, metal, and/or glass, which is supported by structures such as poles or pylons and passing over or nearby navigable waters. (Adapted from Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2012).

† For overhead cables over navigable water, one of the attributes **vertical clearance fixed** or **vertical clearance safe** must be populated.

At least one of the sub-attributes **date end** or **date start** must be populated.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 6.10.1 Overhead cables

If it is required to encode an overhead cable, it must be done using the feature **Cable Overhead**.

The value of the vertical clearance between (high) water level and any fixed overhead obstruction must always be given, where known, on the largest optimum display scale IENC data intended for navigation under the obstruction, and for detailed passage planning. The datum above which clearances are given must be a high water level, preferably Highest Astronomical Tide (HAT), where the tide is appreciable. The value for the vertical clearance must be encoded using the complex attributes **vertical clearance fixed** or **vertical clearance safe**, and sub-attributes populated relevant to the feature.

For power cables or transmission lines carrying very high voltages, an additional vertical clearance of from 2 to 5 metres may be needed to avoid an electrical discharge. When known, the authorised safe clearance (known as the safe vertical clearance), which is the physical clearance minus a safety margin, must be populated using **vertical clearance safe**, having the sub-attribute **vertical clearance value** populated with the safe clearance value.

#### Remarks:

- If it is required to encode telepheric cables, this must be done using **Conveyor** features (see clause 6.9), with attribute CATCON = 1 (aerial cableway).
- Where a cable has radar reflectors at known positions, they may be encoded as separate **Radar Reflector** features (see clause 20.15). If the whole cable is radar conspicuous, the optimum display scale for the IENC data is too small to show individual reflectors, or the positions of the radar reflectors are not known, the **Cable Overhead** should be encoded with attribute **radar conspicuous**.
- In navigable water, overhead cable supports must be encoded, where possible, using a **Pylon/Bridge Support** feature (see clause 6.12), with attribute **category of pylon** = 1 or 2.
- Value 13 (low water) for attribute **vertical datum** is only applicable to enclosed (inland) waterways; and must not be used to indicate the reference datum for vertical clearances in tidal waters.
- If available and considered important for route planning and/or monitoring, the vertical uncertainty associated with encoded vertical clearance values should also be encoded.

Distinction: Cable Area; Cable Submarine; Conveyor; Pylon/Bridge Support.

**Inland specific Encoding Instructions:**

- A) The value given as the **vertical clearance** (VERCLR) shall be provided in metres and indicate the vertical distance between the lowest point of the cable (over the navigable part of the waterway) and a defined high water level (e.g. highest shipping height of water) if available.
- B) If there are multiple cables in the same area, represent only the lowest hanging cable.
- C) Cable supports (**Pylon/Bridge Support** (PYLONS), **category of pylon** (CATPYL) = 1 or 2) closest to the landside of the bank line and those within the water must be coded.
- D) **Feature name** (OBJNAM) should only be used if the name is relevant for navigation; otherwise use **information** (INFORM)
- E) If there is no vertical clearance indicator at a bridge, but there is a gauge which can be used to calculate the vertical clearance of the bridge depending on the water level, it should be encoded in accordance with clause to be amended
- F) An overhead cable connected to a bridge must be encoded if it is within a navigable opening. This feature may be associated to a bridge by a **Bridge Aggregation**.
- G) EUR: If there is a gauge which can be used to calculate the vertical clearance of the bridge, the ISRS location code of the gauge shall be encoded in the attribute **reference gauge** (REFGAG).
- H) Use **name of vertical river datum reference level** (VCRLEV) and **vertical river datum reference level value** (VCRVAL) if the local value and name of vertical river datum reference level (design waterlevel ) is known.
- I) If it is required to encode telepheric cables, this must be done using **Conveyor** features with attribute **category of conveyor** (CATCON) = 1 (aerial cableway), see 6.9.

## 6.11 Pipeline overhead

**IHO Definition: OVERHEAD PIPELINE.** A string of interconnected pipes, supported by pylons and passing over or nearby navigable waters, used for the transport of matter, nowadays mainly oil or gas. (Adapted from IHO Dictionary – S-32 and S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.119, November 2000).

† For overhead pipelines over navigable water, the attribute **vertical clearance fixed** is mandatory.

At least one of the sub-attributes **date end** or **date start** must be populated.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 6.11.1 Overhead pipelines

If it is required to encode an overhead pipeline passing over or nearby navigable waters, it must be done using the feature **Pipeline Overhead**.

The value of the vertical clearance between (high) water level and any fixed overhead obstruction must always be given, where known, on the largest optimum display scale IENC data intended for navigation under the obstruction, and for detailed passage planning. The datum above which clearances are given must be a high water level, preferably Highest Astronomical Tide (HAT), where the tide is appreciable. The value for the vertical clearance must be encoded using the complex attribute **vertical clearance fixed**, and sub-attributes populated relevant to the feature, ).

#### Remarks:

- Where an overhead pipeline is disused, it should be encoded with the attribute **status** = 4 (not in use), and the attributes **category of pipe** and **product** must not be encoded.
- Where a pipeline has radar reflectors at known positions, they must be encoded as separate **Radar Reflector** features (see clause 20.15). If the whole pipeline is radar conspicuous, the optimum display scale for the IENC data is too small to show individual reflectors, or the positions of the radar reflectors are not known, the **Pipeline Overhead** should be encoded with attribute **radar conspicuous**.
- In navigable water, overhead pipeline supports must be encoded, where possible, using a **Pylon/Bridge Support** feature (see clause 6.12), with attribute **category of pylon** = 6 (pipeline pylon).
- Value 13 (low water) for attribute **vertical datum** is only applicable to enclosed (inland) waterways; and must not be used to indicate the reference datum for vertical clearances in tidal waters.

- If available and considered important for route planning and/or monitoring, the vertical uncertainty associated with encoded vertical clearance values should also be encoded.

Distinction: Pipeline Submarine/On Land, Submarine Pipeline Area.

Inland specific Encoding Instructions:

- A) Pipeline supports (PYLONS) closest to the land side of the shoreline and those within the water must be coded.
- B) Pipelines should extend over **Coastline** (COALNE) onto land a short distance.
- C) An overhead pipeline over navigable water has to be encoded unless it is on a bridge, does not affect **vertical clearance fixed** (VERCLR) and **product** (PRODUCT) is not 1 (oil), 2 (gas) or 7 (chemicals).
- D) Overhead pipelines and cables may have significant towers that should be captured as “tower” [**Landmark** (LNDMRK) with **category of landmark** (CATLMK)=17(tower)].
- E) Lights on the towers should be encoded.
- F) The value given as the **vertical clearance fixed** (VERCLR) shall be provided in metres and indicate the vertical distance between the lowest point of the cable (over the navigable part of the waterway) and a defined high water level (e.g. highest shipping height of water) if available.
- G) The vertical clearances must refer to either the vertical datum given in the DSPM VDAT subfield or to the vertical datum given in the Metadata Feature (M\_VDAT) if it is not the same as in the DSPM VDAT subfield.
- H) **Feature name** (OBJNAM) should only be used if the name is relevant for navigation; otherwise use **information** (INFORM).
- I) If there is no vertical clearance indicator at an overhead pipe, but there is a gauge which can be used to calculate the vertical clearance of the overhead pipe depending on the water level, it should be encoded in accordance with clause 22.4.
- J) EUR: If there is a gauge which can be used to calculate the vertical clearance of the overhead pipe, the gauge name shall be encoded in the attribute **reference gauge** (REFGAG). When the attribute **interoperability identifier** of the gauge has been encoded (see **Fehler! Verweisquelle konnte nicht gefunden werden.**), the MRN of the gauge shall be encoded in the attribute **reference gauge** (refgag).
- K) Use **name of vertical river datum reference level** (VCRLEV) and **vertical river datum reference level value** (VCRVAL) if the local value and name of vertical river datum reference level (design waterlevel ) is known.

## 6.12 Pylon/bridge support

**IHO Definition: PYLON/BRIDGE SUPPORT.** A vertical construction consisting, for example, of a steel framework or pre-stressed concrete to carry cables, a bridge, etc. (S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.125, November 2000).

† The attribute **colour pattern** is mandatory for pylons that have more than one value populated for the attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

**6.12.1 Pylons and bridge supports**

The actual position of pylons supporting bridges, pipelines and cables must be indicated on at least the largest optimum display scale IENC data, where they are positioned in the navigable channel or where likely to be useful for position-fixing.

Remarks:

- A **Pylon/Bridge Support** feature of type surface with attribute **water level effect** = 1, 2 or 6 must be covered by a **Land Area** feature of type surface (see clause 5.4).

Distinction: Landmark.

Inland specific Encoding Instructions:

- A) Use **Pylon/Bridge Support** (PYLONS) (P) features to code supports for overhead cables and pipelines (**category of pylon** (CATPYL)=1,2,3).
- B) **Pylon/Bridge Support** (PYLON) (S) must have a **Land Area** (LNDARE) underneath
- C) Pylons and bridge piers in the water and on land closest to the water must be encoded.
- D) For suspension bridges use **category of pylon** (CATPYL) = 4 (bridge pylon/tower)  
For all other bridges use **category of pylon** (CATPYL) = 5 (bridge pier)

### 6.13 Fence/wall

**IHO Definition: FENCE/WALL.** A man-made barrier used as an enclosure or boundary or for protection. (Adapted from Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2013).

#### **S-401 Geo Feature: Fence/Wall (FNCLNE) (O)**

##### **Primitives: Curve**

† The attribute **colour pattern** is mandatory for fences or walls that have more than one value populated for the attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 6.13.1 Fences and walls

If it is required to encode a fence or wall, it must be done using the feature **Fence/Wall**.

##### Remarks:

- No remarks.

Distinction: Fortified Structure.

##### Inland specific Encoding Instructions:

- A) Fences, which are highly relevant for calamity abatement or for the access to navigation facilities, might be encoded.

- B) Floodwalls can be encoded as **Fence/Wall** (FNCLNE), **category of fence** (CATFNC) = 4 (wall), **information text** (INFORM) = floodwall
- C) If a structured external XML-file with more detailed communication information regarding access to the fenced area is available, the reference to the file has to be entered in the **file reference** (TXTDSC) attribute.
- D) If the fence or flood gate has a special time schedule or special operating hours apply, the feature can be combined with a time schedule. For this purpose please refer to the **Time Schedule – In General** feature (tisdge) see 24.6.
- E) US: For **feature name** (OBJNAM) use name of floodwall (e.g., Southwest Jefferson County floodwall)

## 6.14 Railway

IHO Definition: **RAILWAY**. A rail or set of parallel rails on which a train, tram, or rail wagon runs. (Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2010).

### **S-401 Geo Feature: Railway (RAILWY) (C)**

† For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

### 6.14.1 Railways

In urbanized areas, depiction of railways within some miles of the coast is part of the IENC's function in giving a general indication of the degree of land development. In largely undeveloped areas, the depiction of railways to isolated ports draws attention to such ports and may be of some interest for transport purposes. Railways should be encoded on larger and medium optimum display scale IENC data.

Where railways run just inshore of the shoreline, or down to it, together with associated bridges, signal posts and other structure, they provide essential identification features. It should not generally be necessary to depict the smaller associated features - posts, gantries etc.

If it is required to encode a railway, it must be done using the feature **Railway**.

#### Remarks:

- If it is required to encode a railway station, it must be done using a **Building** feature, with attribute **function** = 8 (railway station). On the largest optimum display scale IENC data, the names of railway terminals or main stations may be populated using the attribute **feature name** for the **Building**.
- Abandoned railways (those which are mostly still intact) should be encoded, if required, as **Railway** with the attribute **status** = 4 (not in use).

Distinction: Road; Shoreline Construction; Tunnel.

#### Inland specific Encoding Instructions:

- Switching yards and groups of spur lines should be coded as **Land Region** (LNDRGN) (S) features. If appropriate, code **information text** (INFORM) = Switching yard.
- It is recommended that minimal **Railway** (RAILWY) features be collected in a **Built-up Area** (BUAARE).
- Switching yards may be defined by the external rail lines defining the yard with the **Land Region** (LNDRGN) placed within.
- Include railroads where vessels can see the train lights and traffic control lights from the water.
- Railways on bridges shall not be encoded.

## 6.15 Road

**IHO Definition: ROAD.** A route with a specially prepared surface that is intended for use by wheeled vehicles or pedestrians. (Adapted from Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2013).

### **S-401 Geo Feature: Road (ROADWY) (C)**

#### **Primitives: Curve, Surface**

| -                     | <b>Spatial Association</b> (see clause 25.10)   | <b>Spatial Quality</b>      | Association | 0,*          |

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 6.15.1 Roads and tracks

On the largest optimum display scale continuous coastal series of IENCs, and larger optimum display scale IENC data, all roads and tracks running down to the coastline should be encoded where the optimum display scale permits. Particular attention must be given to local roads serving minor piers, boat hards and landings. Inland, major roads within a few miles of the coast should be encoded to give a general indication of the degree of development, but tracks and all or some of the minor roads should be omitted. In largely undeveloped areas, with very few roads, it may be desirable to encode even minor roads inland.

On smaller optimum display scale IENC data, roads must be omitted.

If it is required to encode a road or track, it must be done using the feature **Road**.

#### Remarks:

- No remarks

Distinction: Causeway; Railway.

#### Inland specific Encoding Instructions:

- Only interstates, highways, major roads and roads providing access to the river should be collected.
- In **Built-up Areas** (BUAARE), with exception to roads providing access to the waterfront, **Roads** (ROADWY) should be restricted to a set of routes representative of the urban layout.
- Roads** should be collected to the limits of the IENC buffer.
- Unless the feature represents an access route useful to vessels, **Road** (ROADWY) features need not have complete or accurate topology.
- Road fragments clipped by the IENC Buffer Zone should be removed.
- Roads** should be encoded as curve features but may also be encoded as surfaces.

- G) Include **Roads** where vessels can see the vehicle lights and traffic control lights from the water.
- H) Roads on bridges shall not be encoded.

## 6.16 Tunnel

**IHO Definition: TUNNEL.** A passage that is open to the atmosphere at both ends, buried under the seabed or laid over the seafloor or bored under the ground or through mountains. (S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.191, November 2000).

### **S-401 Geo Feature: Tunnel (TUNNEL) (C)**

#### **Primitives: Curve, Surface**

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 6.16.1 Tunnels

If it is required to encode a tunnel, it must be done using the feature **Tunnel**.

#### Remarks:

- If there is a waterway inside the tunnel, and the waterway is navigable at the optimum display scale for the IENC data, it must be encoded as if it were a navigable canal (see clause 8.9.1), using the features **Depth Area** or **Dredged Area** in conjunction with the **Tunnel** feature. There must be no **Land Area** feature in the area covering the waterway.
- If it is required to encode a waterway inside a tunnel that is not navigable at the optimum display scale for the IENC data, it must be done using the feature **Canal** (see clause 8.9) in conjunction with the **Tunnel** feature. A **Land Area** feature must cover the tunnel. The complex attributes **horizontal clearance fixed** and **vertical clearance fixed** must not be encoded on the **Tunnel** feature in this case.
- If it is required to encode a tunnel that has no waterway inside it (but a railway, road etc), only the **Tunnel** feature must be encoded (the section of railway or road inside the tunnel must not be encoded), covered by **Land Area**, **Depth Area**, **Dredged Area** or **Unsurveyed Area** features as appropriate. The complex attributes **horizontal clearance fixed** and **vertical clearance fixed** must not be encoded on the **Tunnel** feature in this case.
- Value 13 (low water) for attribute **vertical datum** is only applicable to enclosed (inland) waterways; and must not be used to indicate the reference datum for vertical clearances in tidal waters.
- If available and considered important for route planning and/or monitoring, the vertical uncertainty associated with encoded vertical clearance values should also be encoded.

Distinction: Railway; Road.

**Inland specific Encoding Instructions:**

- A) If a structured external XML-file with more detailed communication information is available, the reference to the file has to be entered in the **file reference** (TXTDSC) attribute.
- B) If the navigable tunnel has a special time schedule or special operating hours apply, the feature can be combined with a time schedule. For this purpose please refer to the **Time Schedule - In General** feature (tisdge) see 24.6.
- C) **Tunnel** (TUNNEL) shall be encoded if:
  - anchoring is prohibited over the tunnel or
  - the tunnel is navigable i.,e. has a **Depth Area** (DEPARE, depare) or **Dredged Area** (DRGARE)
- D) Use **name of vertical river datum reference level** (VCRLEV) and **vertical river datum reference level value** (VCRVAL) if the local value and name of vertical river datum reference level (design waterlevel ) is known.
- E) EUR: If the ISRS Location Code is available, it has to be encoded (see 2.4.13). If a MRN or RIS-ID is available, the attribute **interoperability identifier** must be encoded (refer to **Fehler! Verweisquelle konnte nicht gefunden werden.**)

## 7 Geo Features – Landmarks

### 7.1 Buildings, landmarks, tanks, silos: Common encoding combinations

In the following Table, the symbol '/' indicates that this attribute does not exist for that particular feature class. A blank indicates that the encoder may choose a relevant value for the attribute. The Table contains the most common examples of coding; other coding combinations are possible.

| Feature                            | Feature class | function | category of landmark | product | category of silo/tank |
|------------------------------------|---------------|----------|----------------------|---------|-----------------------|
| Administrative                     | Building      | 18       | /                    | /       | /                     |
| Bank office                        | Building      | 13       | /                    | /       | /                     |
| Boundary mark                      | Landmark      |          | 23                   | /       | /                     |
| Buddhist temple                    | Building      | 25       | /                    | /       | /                     |

**Table 7-1 – Buildings, landmarks, tanks and silos – Encoding**

**Remarks:**

- If it is required to encode an offshore landmark (as defined by the attribute **category of landmark**), the Inland ECDIS or ECS system attribute **in the water** (see clause 30.2) must be populated to ensure the feature is always displayed on the Inland ECDIS or ECS. Where fitted, lights should be encoded as described in Section 19, with the **Building**, **Wind Turbine**, **Landmark** or **Silo/Tank** being used as the structure feature for the relevant light equipment feature(s) (see clause 18.1).
- For encoding wind turbines, see clause 7.4.

## 7.2 Landmark

IHO Definition: **LANDMARK.** Any prominent object at a fixed location on land which can be used in determining a location or a direction. (IHO Dictionary – S-32).

**S-401 Geo Feature: Landmark (LNDMRK) (O)**

**Primitives: Point, Curve, Surface**

*Real World*

*Paper Chart Symbol*

*Inland ECDIS or ECS Symbol*

† The attribute **colour pattern** is mandatory for landmarks that have more than one value populated for the attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 7.2.1 Buildings, landmarks, tanks, silos

Depending on height and the topographic relief, structures considered to be landmarks should be encoded up to several kilometres inland.

Waterfront, landmark and some public buildings should be encoded precisely and individually on the larger optimum display scale IENC data. When representing buildings generally, including urban and other built-up areas, the aim of the compiler must be to create the correct impression of the extent of the built-up area and the density of the buildings.

If it is required to encode a landmark (other than a tank, silo or roofed structure erected or extending over navigable water), it must be done using the feature **Landmark**.

#### Remarks:

- For buildings, see clause 6.2; for silos, tanks and water towers, see clause 7.3. For common encoding combinations, see clause 7.1. For wind turbines, see clause 7.4. For roofed structures such as boathouses erected or extending over navigable water to provide protection for a vessel or its cargo, see clause 8.7. For flare stacks on offshore platforms, see clause 14.1.1.
- The feature association **Structure/Equipment** (see clause 25.12) must only be used with **Landmark** features if the main purpose of the structure is to act as an aid to navigation (for example a lighthouse).
- A water tower must be encoded, where required, using the feature **Silo/Tank** (see clause 7.3).
- A ruined landmark should be encoded in the same way as the feature in good condition, but with attribute **condition** = 2 (ruined).
- Radio and television masts and towers are likely to be visible over long distances and should be encoded as landmarks, even when well inland. They will usually carry air obstruction lights.
- To aid identification of landmarks by the boatmaster it may be useful to add the height of the top of the structure above ground level (**vertical length**) or above the general height datum (**height**).
- Buildings constructed as places of worship often form significant landmarks; their size and structure incorporating towers, spires, cupolas, etc often render them conspicuous. These buildings when

known to be prominent or conspicuous should be encoded up to several miles inland (see Figure 7-1 below, examples (a) and (b)).

- The attribute **category of special purpose mark** should only be used if the **Landmark** is used as the front or rear lead for a transit, clearing line or measured distance, or for a leading line. Values for **category of special purpose mark** such as 16 (leading mark), 17 (measured distance mark) or 41 (clearing mark) in particular should be used for these purposes.
- Values **category of landmark** = 26 (bridge) and 27 (dam) must only be used if the feature is encoded using point geometry; and must not be encoded over navigable water. Bridges and dams encoded using curve or surface geometry must be encoded using features **Bridge** (see clause 6.6) and **Dam** (see clause 8.12) respectively.
- For landmarks located in navigable water, the Boolean attribute **in the water** must be set to *True* to indicate that the feature is to be included in the Inland ECDIS or ECS Base Display. Where such structures are located in the water it is not required to encode any supporting structures (for example piles).
- When a building is shown as a surface, indicating its true shape, and it is required to encode a prominent feature such as a tower or spire that is part of the structure, two features must be created (see Figure 7-1 (b) below):
  - a **Building** feature of type surface for the main building,
  - a **Landmark** feature of type point for the prominent feature

**Figure 7-1 – Landmarks**

- Not all landmarks are visually conspicuous. If a feature is visually conspicuous (that is, it is distinctly and noticeably visible from seaward), the attribute **visual prominence** must be encoded

Distinction: Building; Daymark; Exceptional Navigational Structure, Pylon/Bridge Support; Silo/Tank; Special Purpose/General Beacon; Structure Over Navigable Water, Terminal, Wind Turbine.

Inland specific Encoding Instructions:

- A) Buildings that are visible from the water and that may be used as landmarks shall be collected as **Landmark** (LNDMRK) if possible. Only visually conspicuous landmarks shall be encoded as landmarks. As a result the mandatory attribute CONVIS shall always be 1 (visually conspicuous).
- B) If the landmark serves as a navigational light support, FUNCTN = 33 (light support), it must be encoded with a LIGHTS feature (see 19).
- C) Overhead pipelines and cables may have significant towers that should be captured as “tower” [**Landmark** (LNDMRK) / **category of landmark** (CATLMK) = 17 (tower)].

### 7.3 Silo/tank

**IHO Definition: SILO/TANK.** A large storage structure used for storing loose materials, liquids and/or gases. (Adapted from Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2012).

#### **S-401 Geo Feature: Silo/Tank (SILTNK) (O)**

**Primitives:** Point, Surface

† The attribute **colour pattern** is mandatory for silos or tanks that have more than one value populated for the attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 7.3.1 Tanks, silos

Isolated tanks or gasholders may be good landmarks and should be represented true to scale (that is, as surface) where possible, to enable them to be used as fixing marks. Groups of tanks, as at a refinery, may be useful for general identification of position but cannot usually be used for precise position-fixing because of uncertainty of the location of individual tanks.

If it is required to encode a tank or silo, it must be done using the feature **Silo/Tank**.

#### Remarks:

- For buildings, see clause 6.2; for landmarks, see clause 7.2. For common encoding combinations, see clause 7.1. For roofed structures such as boathouses erected or extending over navigable water to provide protection for a vessel or its cargo, see clause 8.7.
- Groups of silos or tanks (tank farm) in close proximity must be encoded, where required, using the feature **Production/Storage Area** (see clause 7.6). Individual, visually conspicuous silos, or tanks within a tank farm, may be encoded as **Silo/Tank** within the **Production/Storage Area**. Multiple silos contained within a single structure may be indicated using the complex attribute **multiplicity of features**.
- For tanks or silos located in or over navigable water, the Boolean attribute **in the water** must be set to *True* to indicate that the feature is to be included in the Inland ECDIS or ECS Base Display. Where such structures are located in the water it is not required to encode any supporting structures (for example piles).

Distinction: Building; Landmark; Production/Storage Area.

#### Inland specific Encoding Instructions:

- A) Outline silo or tank with circle, square, or rectangle.

## 7.4 Wind turbine

**IHO Definition:** **WIND TURBINE.** A tower and associated equipment that generates electrical power from wind. They can be sited offshore and may be either fixed or floating. (IHO Dictionary – S-32).

**S-401 Geo Feature:** Wind Turbine (**LNDMRK (CATLMK = 19)) (O)**

**Primitives:** Point

† The attribute **colour pattern** is mandatory for bridges that have more than one value populated for the attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 7.4.1 Wind turbines

Wind turbines are generally tall, multi-bladed structures, usually with two or three blades, which may pose as obstacles to navigation if located offshore but are often visible over long distances and therefore useful as visual references. Their purpose is to generate electricity for large communities, or to feed a national grid. They are often in groups (known as wind farms). Floating wind turbines are held in position by ground tackle and consequently may be subject to significant lateral and some vertical movement.

If it is required to encode a wind turbine, it must be done using the feature **Wind Turbine**.

##### Remarks:

- The attribute **elevation** is only applicable for wind turbines on land.
- To aid identification of wind turbines on land by the boatmaster it may be useful to add the height of the top of the structure above ground level (**vertical length**) or above the general height datum (**height**).
- For offshore wind turbines, the Boolean attribute **in the water** must be set to *True* to indicate that the feature is to be included in the Inland ECDIS or ECS Base Display. Where such structures are located in the water it is not required to encode any supporting structures (for example piles).
- For offshore wind turbines (attribute **in the water** = *True*), the attribute **height** is only relevant for fixed turbines, and is referred to the vertical datum (see clause 2.5.7).
- For offshore wind turbines, the attribute **vertical length** is only relevant for floating wind turbines, and is referred to the sea level.
- A ruined wind turbine should be encoded in the same way as the feature in good condition, but with attribute **condition** = 4 (wingless).
- If it is required to encode sites of dismantled offshore wind turbines, this must be done using **Foul Ground** features (see clause 13.7), unless the source indicates that any remaining structure protrudes far enough above the seabed so as to be an obstruction to surface navigation, in which case this must be encoded using an **Obstruction** feature (see clause 13.6).
- If it is required to encode an offshore wind farm, it must be done using the feature **Offshore Production Area** (see clause 14.6). An onshore wind farm must be encoded, where required, using the feature **Production/Storage Area** (see clause 7.6).
- Wind turbines may carry lights (see Section 19) or fog signals (see clause 20.16). Where fitted, lights should be encoded as described in Section 19, with the **Wind Turbine** being used as the structure feature for the light equipment feature(s).
- Value 13 (low water) for attribute **vertical datum** is only applicable to enclosed (inland) waterways; and must not be used to indicate the reference datum for vertical clearances in tidal waters.
- If available and considered important for route planning and/or monitoring, the vertical uncertainty associated with encoded vertical clearance values should also be encoded.
- For encoding offshore safety zones around offshore wind turbines, see clause 14.1.3.

Distinction: Building; Daymark; Landmark; Offshore Platform; Offshore Production Area; Pylon/Bridge Support; Silo/Tank; Special Purpose/General Beacon.

##### Inland specific Encoding Instructions:

- A) Only visually conspicuous wind turbines shall be encoded as **Wind Turbines**. As a result the mandatory attribute **visual prominence** (CONVIS) shall always be 1 (visually conspicuous).

## 7.5 Fortified structure

IHO Definition: **FORTIFIED STRUCTURE**. A structure that is specifically designed or reinforced to provide for defence from armed attack. (Adapted from Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2010).

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 7.5.1 Fortified structures

Some shorelines have prominent defensive structures, often disused, decayed, or used for non-defence purposes. Such structures range from major castles and forts to minor lookout posts and may be the main distinctive features of headlands or stretches of coastline. National regulations permitting, any such features as are likely to be visible from seaward and should be encoded on the largest optimum display scale IENC data.

If it is required to encode a fortified structure, it must be done using the feature **Fortified Structure**.

#### Remarks:

- If it is required to encode a Martello tower, it must be done using **Fortified Structure** with attribute **category of fort** = 5 (fortified tower).
- Where fitted, lights should be encoded as described in Section 19, with the **Fortified Structure** being used as the structure feature for the relevant light equipment feature(s) (see clause 18.1).
- For fortified structures located in navigable water, the Boolean attribute **in the water** must be set to *True* to indicate that the feature is to be included in the Inland ECDIS or ECS Base Display. Where such structures are located in the water it is not required to encode any supporting structures (for example piles).

Distinction: Building; Fence/Wall; Landmark.

Inland specific Encoding Instructions:

- A) Fortified structures shall be encoded as **Fortified Structures** (FORSTC), if they can be seen from the water.

## 7.6 Production/storage area

**IHO Definition: PRODUCTION/STORAGE AREA.** An area on land for the exploitation or storage of natural resources. (S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.124, November 2000).

### **S-401 Geo Feature: Production/Storage Area (PRDARE) (O)**

#### **Primitives: Point, Surface**

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 7.6.1 Production and storage areas

Production or storage areas located in close proximity to the coast are often prominent landmarks used by boatmasters to assist in position-fixing. Features such as quarry faces, stockpiles, power

stations, refineries, timber stacks in timber yards, factories, groups of tanks, groups of wind turbines, and slag heaps should be shown on the largest optimum display scale IENC data.

If it is required to encode production or storage area, it must be done using the feature **Production/Storage Area**.

Remarks:

- If there are individual buildings or equipment features contained within this area, they should be encoded as separate features such as **Building**, **Crane**, **Landmark** or **Silo/Tank** within the **Production/Storage Area** feature of type surface if the optimum display scale of the IENC data permits.
- If visible from seaward, a quarry face should be encoded as for a cliff (see clause 5.1), with attribute **category of slope** = 6 (cliff).

Distinction: Free Port Area; Offshore Production Area.

Inland specific Encoding Instructions:

- A) Only production and storage areas that are connected to transshipment installations and areas that are visually conspicuous should be encoded.
- B) If a structured external XML-file with more detailed communication information is available, the reference to the file has to be entered in the **file reference** (TXTDSC) attribute.

## 8 Geo Features – Ports

### 8.1 Works in progress and projected

An IENC can seldom show the exact state of work under construction because it may not be known by the encoder and, even if known, may be expected to change between IENC updates (see Section 31). Where it is possible to provide the boatmaster with an indication of the status of work under construction, under reclamation or planned, it must be done using the appropriate feature (for example **Shoreline Construction**, **Causeway**, **Dock Area**, **Dry Dock**, **Pipeline Submarine/On Land**), with the attribute **condition** populated as 1 (under construction), 3 (under reclamation) or 5 (planned construction). Where the encoder wishes to provide such information to the boatmaster and the details of the works are not known (nature and extent of the works), this should be done using the feature **Caution Area** (see clause 16.11), with known details of the works encoded using the complex attribute **information** (see clause 2.4.6).

If it is required to provide the boatmaster with an indication of the date to which information regarding the works is current, it must be done using the attribute **reported date** (see clause 27.216).

The coastline existing before the beginning of the works should remain encoded as a **Coastline** or **Shoreline Construction** feature until the completion of the works.

As the works progress and further information is supplied to the producer, IENC datasets should be updated appropriately through the issue of updates to the dataset or publication of New Editions of the dataset (see clause 31.2.3).

On completion of the works, full encoding of the new feature(s) in accordance with the relevant clauses in this document must be achieved, and incorporated in the relevant IENC dataset through the issue of an update to the dataset or publication of a New Edition of the dataset (see Section 31).

#### 8.1.1 Works on land

Features likely to be prominent from seaward should be encoded as described above, where possible. New docks, locks, canals, etc, being excavated should be encoded similarly. The works must be covered by the feature **Land Area** (see clause 5.4) until completion of the works.

#### 8.1.2 Works at sea

Works in the water which will extend the shoreline into the water, where the line of the future shoreline (including piers, etc) is known, must be encoded, where required, as described in clause 8.1 above, using the appropriate features. The existing coastline should remain until the works are completed and the new coastline has been established. The area of reclamation or construction must also be covered by the appropriate feature(s) from the Skin of the Earth. This may be **Depth Area** at commencement of the works, or if the works are planned and have not yet commenced; **Unsurveyed Area** while reclamation/construction is in progress but the area is still covered by water; or **Land Area** where the area of the works has been reclaimed (that is, is always dry).

Works in the water which will be wholly or partly submerged when completed, such as training walls or pipelines must be encoded, if required, using the appropriate feature relevant to the completed feature, in accordance with clause 8.1 above. The appropriately attributed depth information, if known, or **Unsurveyed Area**, must cover the works as appropriate.

Where the extent or nature of the works is unknown, they must be encoded, where required, using the feature **Caution Area** as described in clause 8.1 above.

Because lights and buoys marking the limits of works in the water may be moved without notice, they should be encoded only where it is considered safe to do so. Alternatively, this information may be included by encoding the complex attribute **information**, sub-attribute **text**, for instance, *Outer end marked by red lights*.

## 8.2 Checkpoint

| <b>IHO Definition: CHECKPOINT.</b> An official location at which to register, declare and/or inspect goods and/or people. (Adapted from Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2010). |                           |                                                                                                                    |        |              |

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 8.2.1 Checkpoints

If it is required to encode an official place to register, declare and/or check goods and people, it must be done using the feature **Checkpoint**.

#### Remarks:

- The **Checkpoint** must only be used to encode the function. In addition, if it is required to encode a physical feature (for example building, fence, gate), it must be done using an appropriate feature (for example **Building**, **Landmark**).

Distinction: Custom Zone.

#### Inland specific Encoding Instructions:

- If a structured external XML-file with more detailed communication information is available, the reference to the file has to be entered in the **file reference** (TXTDSC) attribute.
- If an UNLOCODE or an ISRS is available, it must be encoded (see 2.4.13). If a MRN or a RIS-ID is available, the attribute **interoperability identifier** must be encoded (refer to **Fehler! Verweisquelle konnte nicht gefunden werden.**).
- EUR: At least mandatory check points must be encoded.

### 8.3 Hulk

**IHO Definition: HULK.** The hull of a wrecked or condemned ship, from which the fittings and superstructure have usually been removed, which is moored in a permanent position or grounded. It may be abandoned or put to some other use. (Adapted from IHO Dictionary – S-32).

**S-401 Geo Feature: Hulk (HULKES, hulkes) (C)**

**Primitives: Point, Surface**

† The attribute **colour pattern** is mandatory for hulks that have more than one value populated for the attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 8.3.1 Hulks

If it is required to encode a permanently moored ship, it must be done using the feature **Hulk**.

#### Remarks:

- A **Hulk** feature of type surface must not be bound by curve features **Coastline** or **Shoreline Construction**, unless the edge associated with the curve feature is also the boundary of a **Land Area** feature of type surface.
- If it is required to encode a floating production, storage and off-loading vessel, it must be done using the feature **Offshore Platform** (see clause 14.1), with attribute **category of offshore platform** = 8 (floating production, storage and off-loading vessel).
- If it is required to encode a hulk serving the purpose of a floating breakwater, it must be done using a **Hulk** feature, with attribute **category of hulk** = 5 (floating breakwater). If it is required to encode a floating breakwater of any other construction, it must be done using the feature **Shoreline Construction** (see clause 0), with attributes **category of shoreline construction** = 1 (breakwater) and **water level effect** = 7 (floating).

Distinction: Offshore Platform; Shoreline Construction; Wreck.

#### Inland specific Encoding Instructions:

- A) Place shape in location, orientation, and dimensions of the real world object.
- B) If the vessel or facility has a special time schedule or special operating hours apply, the feature can be combined with a time schedule. For this purpose refer to the **Time Schedule – In General** feature (tisdge) 24.6.
- C) If a structured external XML-file with more detailed communication information is available, the reference to the file has to be entered in the **file reference** (TXTDSC) attribute.
- D) If the ISRS Location Code is available it has to be encoded (refer to 2.4.13). If a MRN or a RIS-ID is available, the attribute **interoperability identifier** must be encoded (refer to **Fehler! Verweisquelle konnte nicht gefunden werden.**).
- E) Permanently moored vessels or facilities that are located in navigable water must be encoded.

## 8.4 Pile

**IHO Definition: PILE.** A long heavy timber or section of steel, wood, concrete, etc., forced into the earth or seafloor to serve as a support, as for a pier, or to resist lateral pressure; or as a free standing pole within a marine environment. (IHO Dictionary – S-32).

**S-401 Geo Feature: Pile (PILPNT) (C)**

**Primitives: Point, Curve, Surface**

*Real World*

| - | <b>Spatial Association</b> (see clause 25.10)   | <b>Spatial Quality</b>      | Association | 0,* |

† The attribute **colour pattern** is mandatory for piles that have more than one value populated for the attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 8.4.1 Piles

If it is required to encode a pile or post that is not used as a dolphin or an aid to navigation, it must be done using the feature **Pile**.

##### Remarks:

- Stumps of piles or posts that are dangerous to navigation must be encoded, where required, using **Obstruction** features (see clause 13.6), with attribute **category of obstruction** = 1 (snag/stump), and must not be encoded using **Pile**.
- **Pile** of type curve must only be used for **Pile** having **category of pile** = 5 (piling), which is sometimes termed “row of piles” or “sheet piling”. Point primitive may be used to encode piling for smaller optimum display scale IENC data.
- Stakes and posts that are identified on the source to serve the purpose of aids to navigation must be encoded, where required, using the appropriate beacon feature (for example **Special Purpose/General Beacon**), with attribute **beacon shape** = 1 (stake, pole, perch, post).

Distinction: Cardinal Beacon; Dolphin; Isolated Danger Beacon; Lateral Beacon; Obstruction; Safe Water Beacon; Special Purpose/General Beacon;.

##### Inland specific Encoding Instructions:

- Piles or posts that are situated in the fairway or have a navigational function (e.g. leading post, post as a marker) have to be encoded.
- If the pile or post has a big diameter it should be encoded as a surface.
- The **feature name** (OBJNAM) attribute is mandatory for **Piles** (PILPNT) if the feature is a Structure Feature for a **Leading Light**, **Directional Light**, or **Sector Light**. In other situations, the attribute is optional for **Piles** (PILPNT).

## 8.5 Dyke

**IHO Definition: DYKE.** A dyke (or dike) is an artificial embankment to contain or hold back water. (Adapted from IHO Dictionary – S-32).

### **S-401 Geo Feature: Dyke (DYKCON) (O)**

#### **Primitives: Curve, Surface**

| <p>† Complex attribute <b>feature name</b>, sub-attribute <b>name usage</b> is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.</p> <p>For each instance of <b>fixed date range</b>, at least one of the sub-attributes <b>date end</b> or <b>date start</b> must be populated.</p> <p>For each instance of <b>information</b>, at least one of the sub-attributes <b>file reference</b> or <b>text</b> must be populated.</p> <p><b>8.5.1 Dykes</b></p> <p>Dykes and seawalls are primarily designed to prevent inundation, and generally have regular outlines. If it is required to encode a dyke, it must be done using the feature <b>Dyke</b>.</p> <p><u>Remarks:</u></p> <ul style="list-style-type: none"> <li>• If it is required to encode a dyke whose seaward edge is coincident with the shoreline, it must be done using <b>Dyke</b>, and with a <b>Shoreline Construction</b> feature of type curve along its seaward edge, with no value populated for attribute <b>category of shoreline construction</b>.</li> <li>• When a <b>Dyke</b> feature is of type surface, it must be covered by a <b>Land Area</b> feature.</li> <li>• At large optimum display scales, the dyke crown (the topline of the dyke) may be encoded as a <b>Slope Topline</b> feature (see clause 5.11), with attribute <b>category of slope</b> = 2 (embankment).</li> </ul> <p><u>Distinction:</u> Dam; Sloping Ground; Slope Topline.</p> |                                                 |                                                        |             |                     |

Inland specific Encoding Instructions:

- When a dyke is coincident with the shoreline, it must be encoded as a **Dyke** (DYKCON) .
- The altitude / elevation of the highest point of a dyke above the vertical reference level may be encoded by the attribute HEIGHT
- US: For **feature name** (OBJNAM) use name of levee or levee district.

## 8.6 Shoreline construction

IHO Definition: **SHORELINE CONSTRUCTION**. A fixed artificial structure in the water and/or adjoining the land. It may also refer to features such as training walls, which are not necessarily connected to, nor form part of the shoreline. (S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.154, November 2000, as amended).

For IENCs **Shoreline Construction** includes groins, ground sills, revetments, training walls, boat ramps, slipways, docks, wharfs, lock walls, ice breakers, water intake structures, fenders, landing steps and ladders.

† The attribute **colour pattern** is mandatory for shoreline constructions that have more than one value populated for the attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 8.6.1 Coastline

Natural sections of coastlines, lakeshores and riverbanks should be encoded as **Coastline** (see clause 5.3), whereas artificial sections of coastlines, lakeshores, riverbanks, canal banks and basin borders should be encoded as **Shoreline Construction**. The exception to this general rule is when a lake, river, canal, dock or basin is not navigable at the optimum display scale for the IENC data, in which case the boundaries must not be encoded as **Coastline** or **Shoreline Construction**. These features form the border of the **Land Area** feature.

### 8.6.2 Artificial coastline

If it is required to encode artificial sections of coastlines; or lakeshores, riverbanks, canal banks and basin borders that are navigable at the optimum display scale for the IENC data, this must be done using the feature **Shoreline Construction**.

The largest optimum display scale IENC data should make clear whether any shoreline construction along the shoreline is intended for ships to berth alongside or not. In most instances, the associated detail (name or berth number, depths alongside, dolphins, cargo sheds, cranes or railway lines), in addition to the usually distinctive outline of such features as piers and jetties, will be sufficient to show that ships may come alongside. For shoreline constructions not intended to berth alongside (such as breakwaters and seawalls), an indication that ships do not go alongside may be given by encoding the sloping sides (for example the intertidal portion of the structure). If there is a possibility of misinterpretation by the boatmaster, the danger may be indicated by encoding an Obstruction surface feature (see clause 13.6) with the seaward edge running parallel to the shoreline construction.

Figure 8-1 below represents a shoreline construction such as a mole, including a berthing facility, with a relatively flat top (*abcdlmna*), and sloping sides partly above high water (*nmldefgn*) and partly intertidal (*dopqrhgfed*).

**Figure 8-1 – Shoreline constructions**

**Remarks:**

- Each of the three surface parts of the example shoreline construction above may be encoded as separate **Shoreline Construction** features of type surface; the masked curve (*ang*) must be encoded; and, if part of the **Shoreline Construction** boundary has a different characteristic (for example (*bc*) attribute **category of shoreline construction** = 6 or 15), it should be encoded as a separate **Shoreline Construction** feature of type curve. Alternatively, all the boundaries of the components of the shoreline construction may be encoded as **Shoreline Construction** features of type curve.
- In this example, the shoreline construction surface above the high water line must also be covered by a **Land Area** feature of type surface, and the intertidal shoreline construction surface must also be covered by a **Depth Area** feature of type surface with attribute **depth range minimum value** = -H (see clause 11.6.3).
- Shoreline Construction** features must be broken into their constituent parts where possible, and categorised using attributes such as **category of shoreline construction** and **water level effect** as indicated on the source.
- If the presence of a feature is only indicated on the source by a textual reference, without a clear symbol (for example 'pier', 'groyne', 'post'), it should be encoded using a **Caution Area** feature (see clause 16.11) or an **Information Area** feature (see clause 16.12), with the textual reference encoded using the complex attribute **information** (see clause 2.4.6). **Caution Area** should be used if the information is considered essential for safe navigation.
- Intertidal or submerged artificial rock walls, such as training walls that are not attached to the shoreline, must be encoded, if required, as **Shoreline Construction** using the appropriate value for **category of shoreline construction**, and **water level effect** = 3 (always under water/submerged) or **water level effect** = 4 (covers and uncovers).

**Distinction:** Causeway; Coastline; Dry Dock; Floating Dock; Gridiron; Land Area; Pontoon; Structure Over Navigable Water.

Inland specific Encoding Instructions:

## A) Groin:

- i) If a curve feature is used it should denote the centreline of the structure.
- ii) If large-scale information is available dykes/groins may be encoded as surface features. In that case **Shoreline Construction** (SLCONS, slcons) above the high water (US) / mean water (Europe) line must also be encoded with **Land Area** (LNDARE) (as a surface) and the intertidal **Shoreline Construction** must also be encoded with **Depth Area** (DEPARE, depare) (as a surface).
- iii) If **Shoreline Construction** (SLCONS, slcons) is encoded as a surface, the border with the shore may optionally be masked.
- iv) US: Groins (groynes) and dykes are considered synonymous. Use **feature name** (OBJNAM) (M) = "Groyne" or "Dyke".  
EUR: **Feature name** (OBJNAM) may be used to encode the name and/or operator/owner.
- v) Groins shall be encoded when in or bordering to navigable water.
- vi) **Scale minimum** (SCAMIN) is 45000 for curve features or 22000 for surface features in EUR and 45000 for all in US.

## B) Ground sill

- i) If a curve feature is used it should denote the centreline of the structure.
- ii) If large-scale information is available ground sills may be encoded as surface features. **Shoreline Construction** (SLCONS, slcons) must also be encoded with **Depth Area** (DEPARE, depare) (as a surface).
- iii) If **Shoreline Construction** (SLCONS, slcons) is encoded as a surface, the border with the shore may optionally be masked.
- iv) Ground sills shall be encoded if in navigable water and relevant when using an anchor, e.g. for manoeuvring or emergencies.
- v) **Feature name** (OBJNAM) may be used to encode the name and/or operator/owner.
- vi) **Scale minimum** (SCAMIN) is 45000 for curve features or 22000 for surface features.

## C) Revetment

- i) Delineate outline of known structure. If area limits are unknown, delineate curve feature along the shoreline for the length of the structure.
- ii) Revetment surfaces are generally available in very large scale and detailed vector data. For IENC purposes, revetment surfaces should be slightly generalized to reduce detail, but generalized larger into the channel in the context of safety.
- iii) For loose stone / rip rap, use **category of shoreline construction** (CATSLC) = 8 (rip rap) with **nature of construction** (NATCON) = 3 (loose boulders).
- iv) For concrete mattresses, use **category of shoreline construction** (catslc) = 9 (revetment) with **nature of construction** (NATCON) = 2 (concreted).
- v) Where anchoring or using spuds is prohibited, encode **Restricted Area** (RESARE, resare) for sections of the revetment within the waterway.
- vi) **Scale minimum** (SCAMIN) is 45000 for EUR and 30000 for US.

## D) Training wall

- i) If a curve feature is used it should denote the centreline of the structure.
- ii) If large-scale information is available training wall may be encoded as surface feature. In that case **Shoreline Construction** (SLCONS, slcons) above the high water (US) / mean water (Europe) line must also be encoded with **Land Area** (LNDARE) (as a surface) and the inter-tidal **Shoreline Construction** (SLCONS, slcons) must also be encoded with **Depth Area** (DEPARE, depare) (as a surface).
- iii) If **Shoreline Construction** (SLCONS, slcons) is encoded as a surface, the border with the shore may optionally be masked.
- iv) Inter-tidal or submerged artificial rock walls such as training walls, that are not attached to the shoreline are to be encoded in the following manner: **category of shoreline**

- construction** (CATSLC) = 7 (training wall) with **water level effect** (WATLEV) = 3 (always under water/submerged) or **water level effect** (WATLEV) = 4 (covers and uncovers).
- v) US: Bendway weir: An upstream-angled low-elevation stone sill, built at an elevation low enough to allow normal river traffic to pass over unimpeded, designed to control and redirect currents and velocities throughout a bend of a river. **Feature name** (OBJNAM) (M) = "Bendway Weir"
  - vi) US: For Navigation Weirs see 8.12 (Dam)
  - vii) Training walls shall be encoded if in or bordering to navigable water
  - viii) **Feature name** (OBJNAM) may be used to encode the name and/or operator/owner.
  - ix) **Scale minimum** (SCAMIN) is 45000 for curve features or 22000 for surface features in EUR and 45000 for all in US.
- E) Boat ramp
- i) The boat ramp should be positioned just above the waterline to be clearly seen by the boatmaster.
  - ii) US: Use **status** (STATUS) 8 (private) or 14 (public) to indicate ownership, if known.
  - iii) Refer to **Land Region** (LNDGRN) for boat ramps that are not functional but are common landmarks or locations for reference.
  - iv) Boat ramps shall be encoded when they extend into navigable water
  - v) **Feature name** (OBJNAM) may be used to encode the name + "boat ramp".
  - vi) EUR: If the ISRS Location Code is available, it has to be encoded (refer to 2.4.13). If a maritime MRN or the RIS-ID is available, the attribute **interoperability identifier** has to be encoded (refer to **Fehler! Verweisquelle konnte nicht gefunden werden.**).
  - vii) **Scale minimum** (SCAMIN) is 8000 for EUR and 30000 for US.
- F) Dock / wharf / pier
- i) Land facilities should be represented with **Buildings** (BUISGL) and **Silo / Tank** (SILTNK) features.
  - ii) Docks and wharfs that are bordering to or located in navigable water must be encoded.
  - iii) Use **category of shoreline construction** (CATSLC) as follows:
    - 4, Pier: facility is primarily a structure generally extending perpendicular from shoreline into water.
    - 6, Wharf: facility is primarily a structure parallel to shoreline; use if details of 15 or 16 not known.
    - 15, Solid face wharf: Facility consisting of a solid wall such that water cannot circulate underneath.
    - 16, Open face wharf: Facility supported on piles or other structures that allow free circulation of water under the wharf.
  - iv) **Scale minimum** (SCAMIN) is 45000 for curve features or 22000 for surface features or 8000 for point features.
- G) Fender
- i) Place curve feature to accurately reflect the edge facing vessel traffic.
  - ii) Fenders need not have depictions of structural pylons behind the fender.
  - iii) For fending constructions like cells in waterway used to protect bridge piers, use **category of shoreline construction** (CATSLC) = 14 (fender); if the structure is greater than 3 m in diameter, use a surface feature. A **Land Area** (LNDARE) feature must be encoded underneath, if fender is not floating and **water level effect** (WATLEV) = 2. Use point feature for smaller objects.
  - iv) Fenders of type point or curve must be encoded if the whole object would not be depicted on the chart display otherwise.
  - v) **Scale minimum** (SCAMIN) is 22000 for EUR and 30000 for US.
- H) Slipway

- i) The outside edge of the slipway, both on land and in water, should be depicted as closely to its exact location as possible
  - ii) Slipways that extend into navigable water must be encoded.
  - iii) **Feature name** (OBJNAM) may be used to encode the name of the facility or owner.
  - iv) **Scale minimum** (SCAMIN) is 8000 for EUR and 45000 for US.
- I) Ice breaker
  - i) A **Land Area** (LNDARE) must be encoded beneath an ice breaker.
  - ii) Place **feature name** (OBJNAM), if known, on each ice breaker.
  - iii) Ice Breakers in navigable water shall be encoded. At least the first Ice Breakers on shore in the high water river bed should also be encoded if they are relevant for navigation.
  - iv) **Scale minimum** (SCAMIN) is 45000 for EUR and 60000 for US.
- J) Water intake structure
  - i) Place **feature name** (OBJNAM), if known, on each water intake structure.
  - ii) **Scale minimum** (SCAMIN) is 22000 for EUR and 45000 for US.
- K) Lock wall
  - i) The **Shoreline Construction** (SLCONS, slcons) feature must be coincident with a **Land Area** (LNDARE) feature.
  - ii) This feature must be included in a **Lock Aggregation**.
  - iii) **Scale minimum** (SCAMIN) is 22000 for EUR and 45000 for US.
- L) Supporting structures (e.g., pylons, piers) of landing steps or ladders should be coded when in the water. **Scale minimum** (SCAMIN) is 4000.
- M) Pontoons whose size is not sufficient to create a surface feature must be encoded as point **Shoreline Construction** (SLCONS, slcons) with **category of shoreline construction** (CATSLC) = 4 (pier/jetty). This also applies in case the real dimensions are not known and only a point feature can be encoded.
- N) Buildings that extend into water should be encoded as Dock/Wharf **Shoreline Construction** (SLCONS, slcons) with appropriate **category of shoreline construction** (CATSLC) attribute. Then the building should be placed on that dock.
- O) When a dyke is coincident with the shoreline, it must be encoded as a **Dyke** (DYKCON) and in addition a **Shoreline Construction** (SLCONS, slcons) of type curve, with **category of shoreline construction** (CATSLC) equal "unknown", along its seaward border.

## 8.7 Structure over navigable water

**IHO Definition: STRUCTURE OVER NAVIGABLE WATER.** A roofed structure erected, or partly erected, over a body of water, to provide protection for a vessel or its cargo.

**S-401 Geo Feature: Structure Over Navigable Water**

**Primitives: Surface**

† The sub-attribute **colour pattern** is mandatory for structures over navigable water that have more than one value populated for the sub-attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the Mariner. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 8.7.1 Structures over navigable water

If it is required to encode a roofed structure that is over or partially extends over navigable water to provide protection for a vessel or its cargo, it must be done using the feature **Structure Over Navigable Water**.

The value of the vertical clearance between (high) water level and any fixed overhead obstruction must always be given, where known, on the largest optimum display scale IENC data intended for navigation under the structure, and for detailed passage planning. The datum above which clearances are given must be a high water level. For structures over navigable water, the value for the vertical clearance must be encoded using the complex attribute **vertical clearance fixed**, and sub-attributes populated relevant to the feature.

#### Remarks:

- If it is required to encode the minimum depth for a covered berth or the maximum permitted vessel draught allowed at the berth, this must be done by populating the attributes **minimum berth depth** and **maximum permitted draught**, respectively, for the associated **Berths** feature (see clause 8.14).
- Navigable water under the covering structure must be encoded using the features **Depth Area**, **Dredged Area** or **Unsurveyed Area** (and appropriate **Depth Contour** and **Sounding** features) if the waterway is navigable at the optimum display scale for the IENC data, or using the features **Land Area** if the waterway is not navigable at the optimum display scale for the IENC data.

- The attribute **height** is used, where required, to encode the height of the highest point on the covering structure (see clause 2.5.7).
- The complex attribute **feature name** must only be encoded, if required, where the name of the structure is different to the name of the associated berth.
- Value 13 (low water) for attribute **vertical datum** is only applicable to enclosed (inland) waterways; and must not be used to indicate the reference datum for vertical clearances in tidal waters.
- In navigable water, roof supporting pylons/stanchions must be encoded, where possible, using a **Pylon/Bridge Support** feature (see clause 6.12), with the mandatory attribute **category of pylon** populated as empty (null). The **Pylon/Bridge Support** features must be associated to the **Structure Over Navigable Water** using the association **Roofed Structure Aggregation** (see clause 25.10).
- If possible, it is strongly recommended that an image or graphic of the structure is included, using the attribute **pictorial representation**.
- If available and considered important for route planning and/or monitoring, the vertical uncertainty associated with encoded vertical clearance values should also be encoded.

Distinction: Berth; Building; Harbour Facility; Landmark; Shoreline Construction; Small Craft Facility.

#### Inland specific Encoding Instructions:

- All the objects beneath the roof, building or hall which are important for navigation (e.g. shoreline constructions, mooring facilities, pontoons, cranes, conveyors) have to be encoded additionally.
- Normally it is sufficient to encode the smallest vertical clearance within the area of the object. If there is e.g. a container crane under the roof, it is sufficient to encode the vertical clearance of the crane.
- If the smallest vertical clearance is only valid for a small object beneath a **Structure Over Navigable Water** and it is important to provide information about the bigger vertical clearance under the rest of the building, the vertical clearance has to be encoded for both objects. This should only be done in justified cases to avoid cluttering of the display.
- Place **LIGHTS**, if applicable.
- Use **vertical datum** (verdat) only if vertical datum differs:
  - from DSPM VDAT subfield and
  - from Meta feature **Vertical Datum Of Data** (m\_vdat).
- If there is no vertical clearance indicator near the building, but there is a gauge which can be used to calculate the vertical clearance of the building depending on the water level, it should be encoded in accordance with 22.15.

## 8.8 Causeway

**IHO Definition:** **CAUSEWAY**. A raised way across low or wet ground or water. (IHO Dictionary – S-32).

**S-401 Geo Feature:** Causeway (CAUSWY) (O)

**Primitives:** Curve, Surface

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 8.8.1 Causeways

A causeway is a raised roadway of solid structure built primarily to provide a route across wet ground or an intertidal area.

If it is required to encode a causeway, it must be done using the feature **Causeway**.

##### Remarks:

- No remarks.

Distinction: Dam; Road.

##### Inland specific Encoding Instructions:

- A) Include **Causeways** where vessels can see the car lights and traffic control lights from the water.

## 8.9 Canal

**IHO Definition: CANAL.** An artificial waterway with no flow, or a controlled flow, used for navigation, or for draining or irrigating land (ditch). (IHO Dictionary – S-32).  
This feature is only used for non-navigable canals in Inland ENC's.

### **S-401 Geo Feature: Canal (CANALS) (O)**

#### **Primitives: Curve, Surface**

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 8.9.1 Canals

If it is required to encode a non-navigable canal, it must be done using the feature **Canal**.

#### Remarks:

- If the canal is navigable at the optimum display scale for the IENC data, it must be encoded using the features **Depth Area** or **Dredged Area** (see clauses 11.6 and 11.4), and the canal banks must be encoded using the features **Coastline** or **Shoreline Construction**. The canal must not be encoded as a **Canal** feature. If it is required to encode the name of the canal, it must be done using a **Sea Area/Named Water Area** feature, with attribute **category of sea area** = 51 (canal).
- Where the canal is navigable at the optimum display scale for the IENC data, special consideration should be given to encoding features specific to the canal such as minimum depths within the navigable area; overhead clearances; distances along the canal; and locks and lock gates (and any associated traffic signals).
- If it is required to encode a canal that is not navigable at the optimum display scale for the IENC data, it must be done using **Canal**, covered by a **Land Area** feature. The name of the canal should be encoded using the complex attribute **feature name** on the **Canal** feature.

Distinction: River; Lake; Tideway.

#### Inland specific Encoding Instructions:

- A **Canals** (CANALS) feature may not share the same geospatial position and geometry as a **Sea Area** (SEAARE) feature.
- Canals that can be used for navigation by e.g. pleasure craft should be encoded as **Depth Area** (DEPARE, depare) or **Unsurveyed Area** (UNSARE).

8.10 Distance mark

| <p><u>IHO Definition:</u> <b>DISTANCE MARK.</b> A distance mark indicates the distance measured from an origin and consists of either a solid visible structure or a distinct location without special installation. Usually found on canals. (S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.55, November 2000).<br/>On inland waterway it is used to serve as a reference along the waterway. Due to natural or historic changes in the waterway, the distance can deviate from real distance to the origin.</p> |                            |                                        |                    |                            |

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 8.10.1 Distance marks

Marks which indicate distances along a channel in nautical miles, kilometres or some other unit of measure are considered to be useful on the largest optimum display scale IENC data.

If it is required to encode a distance mark, it must be done using the feature **Distance Mark**.

#### Remarks:

- The origin from which the distance has been measured can be indicated using the sub-attribute **reference location**.
- Where an encoded distance mark has the mandatory Boolean type attribute **distance mark visible** populated as *True*, the **Distance Mark** may also be associated to the structure supporting the mark using a **Structure/Equipment** feature association (see clause 25.12).
- For encoding a measured distance between two transits of marks established on the shore, see clause 15.3.2.

Distinction: Special Purpose/General Beacon.

Inland specific Encoding Instructions:

- A) If the distance deviates from real distance to the origin the simple attributes wtwdis and distance unit of measurement have to be encoded. If the distance mark is referring to a measured distance from an origin the complex attribute measured distance value can be encoded.
- B) **Distance mark** along waterway axis
  - i) EUR: Preferably the waterway axis shall be the middle line between the border lines of the navigable channel rather than the middle line between the riverbanks.
  - ii) Encode the referenced unit of measure using the **distance unit of measurement** attribute
  - iii) The point has to be a connected node.
  - iv) If the ISRS Location Code is available it has to be encoded (refer to 2.4.13). If a maritime MRN or a RIS-ID is available, the attribute **interoperability identifier** must be encoded (refer to **Fehler! Verweisquelle konnte nicht gefunden werden.**).
  - v) Negative values of **waterway distance** (wtwdis) are allowed.
  - vi) EUR: **Distance Marks** along the Waterway Axis must be encoded.
  - vii) **Scale minimum** (SCAMIN) is 8000 for EUR and 120000 for US.
- C) **Distance mark** ashore
  - i) **Distance marks** ashore may be either stones or signs, from the encoding point of view this is no difference.
  - ii) EUR: For hectometre distance marks, use **distance unit of measurement** = 7 (hectometres)  
For kilometre distance marks, use **distance unit of measurement** = 3 (kilometres), e.g., 1147 for km or 4 for hm
  - iii) Negative values of **waterway distance** (wtwdis) are allowed.

## 8.11 Gate

**IHO Definition: GATE.** A structure that may be swung, drawn, or lowered to block an entrance or passageway on a watercourse. (Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2012).

**S-401 Geo Feature: Gate (GATCON, gatcon) (M)**

**Primitives:** Point, Curve, Surface

† For encoded gates that are navigable at the optimum display scale of the IENC data, the attribute **horizontal clearance open** is mandatory.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

The sub-attribute **vertical clearance value** for the complex attribute **vertical clearance open** is mandatory if the sub-attribute **vertical clearance unlimited** is set to *False*.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 8.11.1 Gates

If it is required to encode a gate that controls the flow of water, it must be done using the feature **Gate**. Gates should always be encoded in the closed (to the sea) position.

##### Remarks:

- **Gate** of type surface must also be covered by a **Depth Area**, **Dredged Area**, **Unsurveyed Area** or **Land Area** feature.
- The attribute **depth range minimum value** is used to encode the minimum depth over the sill, where known.
- Value 13 (low water) for attribute **vertical datum** is only applicable to enclosed (inland) waterways; and must not be used to indicate the reference datum for vertical clearances in tidal waters.
- Where the vertical clearance of the gate in the open position is unlimited, the Boolean sub-attribute **vertical clearance unlimited** must be set to *True*.

Distinction: Dry Dock; Floating Dock.

##### Inland specific Encoding Instructions:

- Linear **Gates** (GATCON, gatcon) features should follow the edge of **Depth Area** (DEPARE, depare) that defines the lock chamber. Surface **Gate** (GATCON, gatcon) features have to be placed on a **Depth Area**.
- Encode attribute **vertical datum** (VERDAT) only if vertical datum differs:
  - from DSPM VDAT subfield and
  - from Metadata feature **Vertical Datum of Data** (M\_VDAT) attribute and specific for inland navigation or in case of a lifting barrage gate that restricts the air draught.
- Vertical clearance value** (VERCLR) has to be encoded in case of a lifting lock door, lifting barrage gate or gate-frame that restricts the air draught of passing vessels.
- waterway distance** (wtwdis) and **distance unit of measurement** shall be encoded if the attribute **vertical clearance value** (VERCLR) is used.

- E) Use **name of vertical river datum reference level** (vcrlev) and **vertical river datum reference level value** (vcrval) if the local value and name of vertical river datum reference level (design waterlevel) is known.
- F) EUR: A RIS-ID is assigned to each single **Gate** (GATCON, gatcon) feature and to the **Nautical Information** feature associated to the entire lock (refer to 2.4.13 and **Fehler! Verweisquelle konnte nicht gefunden werden.**).
- G) Lock gates
  - i) All lock gates must be encoded.
- H) Opening barrage
  - i) For non-navigable parts of a flood barrage use **Dam** (DAMCON) unless the current has an influence on navigation. For parts of a barrier/ flood barrage that are navigable at certain water levels or have an influence on navigation use **Gate** (GATCON, gatcon) (see instruction D).
  - ii) All objects of one Flood Barrage must be associated by a **Barrage Association**iii) The object name of a barrage is assigned to the associated **Nautical Information** feature using **feature name** (OBJNAM).
  - iii) If a structured external XML-file with more detailed communication information is available, the reference to the file has to be entered in the **file reference** (TXTDSC) attribute.
  - iv) Opening barrages shall be encoded if they are located in navigable water.
- I) A bridge over a lock gate or barrier / flood barrage needs to be encoded separately with a **Bridge** feature (see 6.6)

## 8.12 Dam

**IHO Definition: DAM.** A barrier to check or confine anything in motion; particularly one constructed to hold back water and raise its level to form a reservoir, or to prevent flooding. (IHO Dictionary – S-32).

### **S-401 Geo Feature: Dam (DAMCON) (O)**

#### **Primitives: Curve, Surface**

† The attribute **colour pattern** is mandatory for dams that have more than one value populated for the attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 8.12.1 Dams

If it is required to encode a dam, weir or flood barrage, it must be done using the feature **Dam**; or as a **Landmark** feature (see clause 7.2) if the dam has geometry of type point.

#### Remarks:

- **Dam** features must be covered by a **Land Area** feature.
- The geometry of the dam includes any gates. Gates should be encoded as separate **Gate** features.
- If it is required to encode a dam whose seaward edge is coincident with the coastline, it must be done using **Dam**, with a **Shoreline Construction** feature of type curve along its seaward edge, with no value populated for the attribute **category of shoreline construction**.
- If it is required to encode a submerged weir, it should be done using a **Dam** feature, with attribute **water level effect** = 3 (always under water/submerged).

### 8.12.2 Flood barrages

If it is required to encode the fixed part of a flood barrage, and the flood barrage is inside an area which is navigable at the optimum display scale for the data, it must be done using a **Dam** feature, with attribute **category of dam** = 3 (flood barrage), and must be covered by a **Land Area** feature. If it is required to encode the opening part of the flood barrage, it must be done using a **Gate** feature, with attribute **category of gate** = 2 (flood barrage gate), and must be covered by a **Depth Area** feature.

When an encoded flood barrage is inside an area that is not navigable at the optimum display scale for the IENC data, the gates need not be encoded. In this case, the **Dam** feature must go all the way across the river or lake.

#### Remarks:

- None.

Distinction: Causeway; Dyke; Oil Barrier; Road.

**Inland specific Encoding Instructions:**

- A) If appropriate, place a **Restricted Area** (RESARE, resare) around dam, extending on both sides of the dam the length of the lock guidewall or the area that is marked by buoys.
- B) Use **feature name** (OBJNAM) option according to most commonly accepted name.
- C) US: Navigation Weir - a low dam built across a river to raise its level or divert its flow; constructed at an elevation low enough to allow river traffic to pass over it unimpeded during certain times of year. **Category of dam** (CATDAM) = 1 (weir) with appropriate **nature of construction** (NATCON).
- D) US: INFORM = "All waters immediately above and below the dam are designated as restricted areas."
- E) EUR & RU: If there are buoys or notice marks to mark the extent of the area, they have to be encoded.
- F) For openings in a barrier that are navigable at certain water levels see 8.11 **Gate**.
- G) All features which belong to a dam / barrier must be combined into one **Flood Barrage** association.
- H) The feature name of a barrage is assigned to the **Nautical Information** feature.
- I) If a structured external XML-file with more detailed communication information is available, the reference to the file has to be entered in the **file reference** (TXTDSC) attribute.

### 8.13 Crane

**IHO Definition: CRANE.** A machine for lifting, shifting and lowering objects or materials by means of a swinging boom or with a lifting apparatus supported on an overhead track. (Defence Geospatial Information Working Group; Feature Data Dictionary Register, 2010).

#### **S-401 Geo Feature: Crane (CRANES, cranes) (C)**

##### **Primitives: Point, Surface**

† The attribute **colour pattern** is mandatory for cranes that have more than one value populated for the attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 8.13.1 Cranes

If it is required to encode a crane, it must be done using the feature **Crane**.

#### Remarks:

- The purpose of charting these features is primarily to assist the boatmaster in identifying particular berths, etc.
- The complex attribute **orientation** is used, where required, to encode the angular distance from true north to the axis of the crane's jib (generally perpendicular to the wharf).
- The position of a sheerleg or a travelling crane is defined as its resting position. If it is required to encode the track, it must be done using the feature **Railway** (see clause 6.14).
- Where fitted, lights should be encoded as described in Section 19, with the **Crane** being used as the structure feature for the relevant light equipment feature(s) (see clause 18.2).
- For cranes located in navigable water, the Boolean attribute **in the water** must be set to *True* to indicate that the feature is to be included in the Inland ECDIS or ECS Base Display. Where such structures are located in the water it is not required to encode any supporting structures (for example piles, stilts).
- Value 13 (low water) for attribute **vertical datum** is only applicable to enclosed (inland) waterways; and must not be used to indicate the reference datum for vertical clearances in tidal waters.
- If available and considered important for route planning and/or monitoring, the vertical uncertainty associated with encoded vertical clearance values should also be encoded.

Distinction: Conveyor.

#### Inland specific Encoding Instructions:

- A) For surface features, delineate the perimeter of the crane.
- B) If a crane extends over navigable water it has to be encoded.
- C) EUR: If the ISRS Location Code is available, it must be encoded (refer to 2.4.13). If a maritime MRN or a RIS-ID is available, the attribute **interoperability identifier** must be encoded (refer to **Fehler! Verweisquelle konnte nicht gefunden werden.**).
- D) Use **name of vertical river datum reference level** (vcrlev) and **vertical river datum reference level value** (vcrval) if the local value and name of vertical river datum reference level (design waterlevel ) is known.

## 8.14 Berth

**IHO Definition: BERTH.** A place, generally named or numbered, where a vessel may moor or anchor. (IHO Dictionary – S-32).

For IENCs: A designated named or numbered place at the bank of the river or in a harbour basin for the mooring of vessels

### **S-401 Geo Feature: Berth (berths) (M)**

**Primitives:** Point, Curve, Surface

<sup>†</sup> Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 8.14.1 Berths

Numbered, named or lettered berth information must be encoded on at least the largest optimum display scale IENC data, in order to assist the boatmaster in berthing activities within ports and harbours.

If it is required to encode a berth, it must be done using the feature **Berth**.

#### Remarks:

- The berth encodes the named place where a vessel can be moored adjacent to a shoreline construction. The shoreline construction itself should be encoded using the feature **Shoreline Construction** (see clause 8.6).
- The attributes **horizontal clearance length** and **horizontal clearance width** are used to encode the regulatory length and width of the navigable part of the berth as declared by a competent authority, where known.
- The mandatory complex attribute **feature name** is used to encode the name or number of the berth. The attributes **minimum berth depth** and **maximum permitted draught** are used to encode the shoalest physical depth and maximum draught permitted at the berth respectively, where known.
- Terminal facilities (for example container, tanker, ferry) must be encoded, where required, using the feature **Harbour Facility** (see clause 22.7).
- Landing places for boats should be encoded as small craft facilities (see clause 22.8).
- For encoding anchor berths, see clause 16.5.

Distinction: Anchor Berth; Bollard; Dock Area; Dolphin; Mooring Area; Mooring Buoy; Shoreline Construction; Structure Over Navigable Water; Terminal; Vehicle Transfer.

#### Inland specific Encoding Instructions:

- A) For **Anchorage Area** see 16.3.
- B) Where a berth may only be used for a limited period the duration should be indicated in **information** (INFORM). If the berth has special operating hours, the **Berth** feature can be combined with a **Time Schedule In General** (tisdge) feature (24.6)
- C) EUR: The linear extent of **Berth** feature is defined by markers or notice marks (signs E.5 – E.5.15, E.6, E.7 or E.7.1) on the bank.
- D) Within port areas it is allowed to encode **Berths** as curve features.
- E) Land facilities should be represented with **Building** (BUISGL) and **Silo / Tank** (SILTNK) or **Harbor Facility** (HRBFAC, hrbfac) features.
- F) If a structured external XML-file with more detailed communication information is available, the reference to the file has to be entered in the **file reference** (TXTDSC) attribute.
- G) The class of dangerous goods in accordance with ADN and the applicable police regulations: 1 (one blue light / cone, signs E.5.5, E.5.9, E.5.13), 2 (two blue lights / cones, signs E.5.6, E.5.10, E.5.14), 3 (three blue lights / cones, signs E.5.7, E.5.11, E.5.15), 4 (no blue lights / cones, signs E.5.4, E.5.8, E.5.12). Dangerous goods in accordance with inland waterway regulations of the Russian Federation: 5 (one red light / cone top down).
- H) EUR: If the ISRS Location Code is available, it has to be encoded (refer to 2.4.13). If a maritime MRN or a RIS-ID is available, the attribute **interoperability identifier** must be encoded (refer to **Fehler! Verweisquelle konnte nicht gefunden werden.**).
- I) If the **depth range minimum value** (DRVAL1) attribute is used, **quality of vertical measurement** (QUASOU), **uncertainty fixed** (SOUACC) and **vertical datum** (VERDAT) should also be provided.
- J) Berth without transshipment / Fleeting Areas
  - i) US:
    - First Class Landing: An area providing tie-ups and at least 9 feet of water depth during low water level

- Second Class Landing: An area providing tie-ups and at least 9 feet of water depth during normal pool level

Mandatory attributes:

**Category of berth** (CATBRT) = 7 (first class landing) or 8 (second class landing)

**Feature name** (OBJNAM) = "First Class Landing" or "Second Class Landing" in both **Berth** (berths) and **Sea Area** (SEAARE).

- ii) US: Fleeting Areas: Area in waterway designated for temporary barge mooring. Mandatory attribute: **category of berth** (CATBRT) = 6 (fleeting area).
- iii) The **category of berth** 10 (waiting berth) should be used for a berth that is dedicated for vessels waiting for a bridge opening, lockage or other infrastructure. Even if a berth is dedicated to waiting, but other use (e.g. resting, staying over night) can be allowed by the operator of the infrastructure, it should also be encoded as waiting berth. A waiting berth of a lock or movable bridge shall be linked to the navigational structure for which vessels using this berth are waiting by the **Lock Aggregation, Bridge Aggregation**. For other types of infrastructure the type and name of the infrastructure should be encoded in the complex attributes **feature name** or **information**.  
A lock, movable bridge, harbour basin, transshipment installation etc. can be connected to several waiting berths, but a waiting berth can also be connected to e.g. several locks.
- iv) If the width of **Anchorage Area** (achare) is not defined by notice marks, consider using 110'/33.55 m (approximately three barge widths).

K) Transshipment berth

- i) If the width of a **Berth** is not defined by notice marks, consider using 110' / 33,55 m (approximately three barge widths).

## 8.15 Dolphin

IHO Definition: **DOLPHIN**. A post or group of posts, used for mooring or warping a vessel, or as an aid to navigation. The dolphin may be in the water, on a wharf or on the beach. (Adapted from IHO Dictionary – S32).

† The attribute **colour pattern** is mandatory for dolphins that have more than one value populated for the attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 8.15.1 Dolphins

If it is required to encode a dolphin, it must be done using the feature **Dolphin**.

#### Remarks:

- If it is required to encode a dolphin beacon, this must be done using a beacon feature (see clauses 20.9-12), or a **Pile** feature (see clause 8.4).
- Dolphins that are disused and/or have fallen into disrepair must be encoded, where required, using **Obstruction** or **Pile** features.

Distinction: Pile; Shoreline Construction; Special Purpose/General beacon; Special Purpose/General Buoy;.

#### Inland specific Encoding Instructions:

- Surface feature should be used for structures greater than 3 metres in diameter.
- Use **Land Area** (LNDARE) beneath feature if not floating and code **water level effect** (WATLEV) = 2 for **Dolphin**.
- Place **feature name** (OBJNAM), if known, on each **Dolphin**.
- In an instance when a barge has been sunk near the shoreline and dolphins permanently attached to it, code each dolphin.

- E) In the event that a **Dolphin** (S) is used, it is also allowed to encode an additional **Dolphin** (P) to help aid in the display for planning purposes. The **DOLPHIN** (P) should be placed inside the **Dolphin** (S) on the side closest to the navigation channel.
- F) **Dolphins** that are located in navigable water must be encoded.

## 8.16 Bollard

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 8.16.1 Bollards

If it is required to encode a bollard, it must be done using the feature **Bollard**.

Remarks:

- The identifier of designator for a bollard must be encoded, where required, using the complex attribute **feature name**.
- Bollards should be associated to the feature on which they are mounted using the association **Structure/Equipment** (see clause 25.12).

Distinction: Pile; Shoreline Construction.

Inland specific Encoding Instructions:

## 8.17 Dry dock

**IHO Definition: DRY DOCK.** An artificial basin fitted with a gate or caisson, into which vessels can be floated and the water pumped out to expose the vessel's bottom. Also called graving dock. (IHO Dictionary – S-32).

### **S-401 Geo Feature: Dry Dock (DRYDOC) (O)**

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 8.17.1 Dry docks

A dry dock (or graving dock) is an artificial basin into which a ship can be floated for cleaning and repairs. The entrance can be closed by gate or caisson and the water pumped out to expose the vessel's bottom.

If it is required to encode a dry dock, it must be done using the feature **Dry Dock**.

**Remarks:**

- A dry dock must also be covered by a **Land Area** feature. The boundary of a dry dock must not be encoded as a separate feature (**Coastline** or **Shoreline Construction**), except for the gate feature (**Gate**), which may be encoded.
- The attributes **horizontal clearance length** and **horizontal clearance width** are used to encode the regulatory length and width of the navigable part of the dry dock when the gate is open as declared by a competent authority, where known. If required, the minimum physical length and width of the dry dock itself must be populated using the attributes **horizontal length** and **horizontal width**.
- The attributes **depth range minimum value** and **maximum permitted draught** are used to encode the shoalest physical depth in the dock when the gate is open and maximum draught permitted in the dock respectively, where known.

**Distinction:** Dock Area; Floating Dock; Gate; Shoreline Construction.

**Inland specific Encoding Instructions:**

- A) Encode outline of entire structure.
- B) If a structured external XML-file with more detailed communication information is available, the reference to the file has to be entered in the **file reference** (TXTDSC) attribute.

## 8.18 Floating dock

**IHO Definition: FLOATING DOCK.** A form of dry dock consisting of a floating structure of one or more sections which can be partly submerged by controlled flooding to receive a vessel, then raised by pumping out the water so that the vessel's bottom can be exposed. (IHO Dictionary – S-32).

† The attribute **colour pattern** is mandatory for floating docks that have more than one value populated for the attribute **colour**.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of information, at least one of the sub-attributes file reference or text must be populated.

### 8.18.1 Floating docks

If it is required to encode a floating dock, it must be done using the feature Floating Dock.

#### Remarks:

- A **Floating Dock** feature must also be covered by **Depth Area**, **Dredged Area** or **Unsurveyed Area** features. The boundary of a **Floating Dock** feature of type surface must not be encoded as a separate feature (**Coastline** or **Shoreline Construction**).
- The attributes **horizontal clearance length** and **horizontal clearance width** are used to encode the regulatory length and width of the navigable part of the floating dock as declared by a competent authority, where known. If required, the minimum physical length and width of the dry dock itself must be populated using the attributes **horizontal length** and **horizontal width**.
- The attribute **depth range minimum value** is used to encode the shoalest depth of the dock when flooded, and the attribute **maximum permitted draught** is used to encode the maximum draught permitted in the dock, where known.

Distinction: Dock Area; Dry Dock.

#### Inland specific Encoding Instructions:

- A) If the water depth in the floating dock is referred to an inland waterway reference level, or if the available length and/or width of the dock is different from the physical length/width of the chamber, a **Depth Area** has to be coded underneath.
- B) If the **Floating Dock** has a special time schedule or special operating hours apply, the feature can be combined with a time schedule. For this purpose please refer to the **Time Schedule – In General** feature (tisdge) 24.6.
- C) If a structured external XML-file with more detailed communication information is available, the reference to the file has to be entered in the **file reference** (TXTDSC) attribute.
- D) **Floating Docks** that are permanently moored at a fixed location must be encoded.
- E) Use **name of Sounding datum reference level** (sdrlev) and **sounding datum reference level value** (sdrval) if the local value and name of vertical river datum reference level (design waterlevel ) is known.
- F) Use **name of vertical river datum reference level** (vcrlev) and **vertical river datum reference level value** (vcrval) if the local value and name of vertical river datum reference level (design waterlevel ) is known.
- G) If the usable horizontal clearance of length and width are distances which are provided by the competent authority for safe navigation, they must be encoded with **horizontal clearance length** (horcll) and **horizontal clearance width** (horclw).

## 8.19 Pontoon

**IHO Definition: PONTOON.** A floating structure, usually rectangular in shape which serves as landing, pier head, bridge support, etc. (Adapted from IHO Dictionary – S-32).

### **S-401 Geo Feature: Pontoon (PONTON, ponton) (C)**

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 8.19.1 Pontoons

If it is required to encode a pontoon, it must be done using the feature **Pontoon**.

##### Remarks:

- A **Pontoon** feature must also be covered by **Depth Area**, **Dredged Area** or **Unsurveyed Area** features. A **Pontoon** feature of type surface must not be bound by curve features **Coastline** or

**Shoreline Construction**, unless the edge associated with the curve feature is also the boundary of a **Land Area** feature of type surface.

Distinction: Bridge; Dolphin; Mooring Buoy; Shoreline Construction.

Inland specific Encoding Instructions:

- A) Place surface in location, orientation, and dimensions of the Real world object.
- B) If the landing stage or pontoon has a special time schedule or special operating hours apply, the feature can be combined with a time schedule. For this purpose please refer to the **Time Schedule - In General** feature (tisdge) (24.6).
- C) If a structured external XML-file with more detailed communication information is available, the reference to the file has to be entered in the **file reference** (TXTDSC) attribute.
- D) EUR: If the ISRS Location Code is available it has to be encoded (refer to 2.4.13). If a maritime MRN or a RIS-ID is available, the attribute **interoperability identifier** must be encoded (refer to **Fehler! Verweisquelle konnte nicht gefunden werden.**).
- E) A landing stage and pontoon shall be encoded if a hazard to navigation or when passing vessels are required to reduce speed.

## 8.20 Dock area

**IHO Definition: DOCK AREA.** An artificially enclosed area within which ships may moor and which may have gates to regulate water level. (S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.56, November 2000).

### **S-401 Geo Feature: Dock Area (DOCARE) (O)**

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 8.20.1 Tidal and non-tidal basins

If it is required to encode a non-navigable dock area, it must be done using the feature **Dock Area**.

#### Remarks:

- If the dock is navigable at the optimum display scale of the IENC data, it must be encoded using the features **Depth Area**, **Dredged Area** or **Unsurveyed Area** (see clause 11.6.4), and the geo features making up the dock limits must be encoded using appropriate features such as **Coastline**, **Shoreline Construction** or **Gate**. The dock must not be encoded as **Dock Area**. If it is required to encode the name of the dock, it must be done using the feature **Sea Area/Named Water Area**.
- If it is required to encode a dock which is not navigable at the optimum display scale of the ENC data, it must be done using the feature **Dock Area**, covered by a **Land Area** or **Unsurveyed Area** feature. The name of the dock should be encoded using the complex attribute **feature name** on the **Dock Area**. The boundary of a dock must not be encoded as a separate feature (for example **Coastline**, **Shoreline Construction**), except for the gate feature (**Gate**) for a wet dock, which may be encoded.
- The complex attribute **horizontal clearance fixed** is used to encode the size of the entrance to the dock area, where required.
- The attributes **horizontal clearance length** and **horizontal clearance width** are used to encode the regulatory length and width of the navigable part of the dock area as declared by a competent authority, where known.
- In a non-tidal basin (wet dock), depths may refer to a sounding datum different from that in open waters. If this area is navigable at the optimum display scale of the IENC data, the value of this datum must be encoded using the Meta feature **Sounding Datum**, with attribute **vertical datum** = 24 (local datum), coincident with the area covered by the dock.
- In reality, smaller named, non-navigable dock areas (at the optimum display scale of the IENC data) may be included in major navigable dock areas, with different names or characteristics. To encode this fact, sea areas (**Sea Area/Named Water Area**) may overlap a **Dock Area**.

Distinction: Berth; Cargo Transhipment Area; Dry Dock; Floating Dock; Gate; Harbour Area (Administrative); Harbour Facility.

#### Inland specific Encoding Instructions:

---

## 8.21 Gridiron

**IHO Definition: GRIDIRON.** A structure in the intertidal zone serving as a support for vessels at low stages of the tide to permit work on the exposed portion of the vessel's hull. (IHO Dictionary – S-32).

### **S-401 Geo Feature: Gridiron (GRIDRN) (O)**

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 8.21.1 Gridirons

If it is required to encode a gridiron, it must be done using the feature **Gridiron**.

#### Remarks:

- Due to gridirons normally being located in intertidal areas, it is only required to encode **Gridiron** on the largest optimum display scale IENC data.

Distinction: Dry Dock; Floating Dock.

#### Inland specific Encoding Instructions:

- The vertical distance from seabed to the highest point of the gridiron should be encoded in **vertical length** (VERLEN).
- Vertical length** measurements (VERLEN) do not require a datum.

## 8.22 Lock basin

**IHO Definition: LOCK BASIN.** A wet dock in a waterway, permitting a ship to pass from one level to another. (IHO Dictionary – S-32).

### **S-401 Geo Feature: Lock Basin (lokbsn) (M)**

#### **Primitives: Surface**

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 8.22.1 Locks

#### Remarks:

- If the lock is navigable at the optimum display scale of the IENC data, it must be encoded using the features **Depth Area** or **Dredged Area** (see clause 11.6.4), and the geo features making up the limits of the lock must be encoded using appropriate features such as **Coastline**, **Shoreline Construction** or **Gate**. If it is required to encode a lock that is not navigable at the optimum display scale of the IENC data, it must be done using **Lock Basin**, covered by a **Land Area** or **Unsurveyed Area** feature. The name of the lock should be encoded using the complex attribute **feature name** on the **Lock Basin** feature.
- The gates should be encoded as a **Gate** feature (see clause 8.11) with attribute **category of gate** = 4 (lock gate) or 3 (caisson). For smaller optimum display scale IENC data, a lock may be encoded using **Gate** only, without using **Lock Basin**.

Distinction: Canal; Gate.

#### Inland specific Encoding Instructions:

- If the usable horizontal clearance of length and width are distances which are provided by the competent authority for safe navigation, they must be encoded with **horizontal clearance length** (horcl) and **horizontal clearance width** (horclw).
- The minimum physical length and width given by the building itself must be encoded with **horizontal length** (HORLEN) and **horizontal width** (HORWID).
- All features of one lock must be associated to a **Lock Aggregation**.
- EUR: A RIS-ID is assigned to each single **Lock Basin** (lokbsn)= feature and to the **Nautical Information** feature associated with the entire lock (refer to 2.4.13 and **Fehler! Verweisquelle konnte nicht gefunden werden.**)
- If the **Lock Basin** has a special time schedule or special operating hours apply, the feature can be combined with a time schedule. For this purpose please refer to the **Time Schedule – In General** feature (tisdge) (24.6)
- If a structured external XML-file with more detailed communication information is available, the reference to the file has to be entered in the **file reference** (TXTDSC) attribute.

## 8.23 Mooring trot

**IHO Definition: MOORING TROT.** A mooring is a place where a vessel may be secured. (IHO Dictionary – S32).

A mooring trot is a mooring that is composed of ground tackle, mooring cables, buoys and mooring berths on junction cables.

### **S-401 Geo Feature: Mooring Trot (C\_AGGR) €**

| -                     | <b>Spatial Association</b> (see clause 25.10)     | <b>Spatial Quality</b>                                   | Association | 0,*          |

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 8.23.1 Mooring trots

**Figure 8-2 – Mooring trot**

A complete mooring trot is composed of ground tackle, mooring cables, buoys and mooring berths on junction cables. The following remarks refer to the annotations in Figure 8-2 above:

- (a) Ground tackle should be encoded using **Obstruction** features (see clause 13.6), with attribute **category of obstruction** = 9 (ground tackle).
- (b) Mooring cables should be encoded using **Cable Submarine** features (see clause 14.2), with attribute **category of cable** = 6 (mooring cable).
- € Buoys should be encoded using **Mooring Buoy** features.
- (d) Mooring berths should be encoded using **Berth** features.
- € Junction cables should be encoded using **Cable Submarine** features, with attribute **category of cable** = 9 (junction cable).

All these features should be aggregated in a **Mooring Trot** feature, using the association **Mooring Trot Aggregation** (see clause 25.7), with the name of the mooring trot being populated using the complex attribute **feature name** for the **Mooring Trot**.

Remarks:

- If it is required to encode the name of a mooring trot, the **Mooring Trot** should be encoded using geometry of type surface. The extent of the surface should cover the extent of all the components of the mooring trot.
- If it is required to encode the extent of an unnamed mooring trot, this may be done using a **Mooring Trot** feature having no geometry.
- Names or numbers of individual moorings within the mooring trot must be encoded using the attribute **feature name** on the relevant **Berth** feature.

Distinction: Berth; Mooring Buoy; Mooring Area.

Inland specific Encoding Instructions:

- A) Mooring trots have to be encoded if they are in navigable water.

## 8.24 Exceptional Navigation Structure

| <b>IHO Definition:</b> An exceptional navigational construction like aqueduct, lift-lock, etc.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                             |                                                                                                                                                                                                                   |      |              |

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

Inland specific encoding instructions:

- A) **depth range minimum value** (DRVAL1) represents the minimum operating depth of the structure.
- B) The exceptional structure does not carry information about the vertical clearance underneath. If the exceptional structure crosses navigable water (e.g., aqueduct) a **Bridge** feature must be encoded to provide the vertical clearance underneath.
- C) Use **vertical datum (VERDAT)** only if vertical datum differs:
  - from DSPM SDAT subfield and
  - from Metadata feature **Sounding Datum** (m\_sdat) attribute
- D) Note: The vertical datum is the reference of the minimum operation depth of the exceptional structure.
- E) If the exceptional navigational structure has a special time schedule or special operating hours apply, the feature can be combined with a time schedule. For this purpose please refer to the **Time Schedule – In General** feature (tisdge) 24.6.

- F) Restricted vertical clearance within the lock chamber should be encoded by the respective features (e.g., **Gate** (GATCON, gatcon), **Span Fixed** (bridge), **Span Opening** (bridge), **Cable Overhead** (cblohd))
- G) EUR: If the ISRS Location Code is available it shall be encoded (refer to 2.4.13. If a maritime MRN or RIS-ID is available, the attribute **interoperability identifier** must be encoded (refer to **Fehler! Verweisquelle konnte nicht gefunden werden.**).
- H) For Notice Marks on aqueducts see 20.17.
- I) All features which belong to an **Exceptional Navigation Structure** must be combined into one **Exceptional Navigation Structure** aggregation.
- J) The object name of an **Exceptional Navigational Structure** complex is assigned to the **Nautical Information** feature using **feature name** (OBJNAM) if it is not sufficient to encode the **feature name** of the **Exceptional Navigation Structure** itself..
- K) If a structured external XML-file with more detailed communication information is available, the reference to the file has to be entered in the **file reference** (TXTDSC) attribute.
- L) For encoding an Aqueduct: If the usable horizontal clearance of width is a distance which is provided by the competent authority for safe navigation, it must be encoded with **horizontal clearance width** (HORCLW).
- M) Use **name of sounding datum reference level** (SDRLEV) and **sounding datum reference level value** (SDRVAL) if the local value and name of vertical river datum reference level (design waterlevel) is known.

## 8.25 Harbour Basin

**IHO Definition:** An enclosed area of water surrounded by quay walls constructed to provide means for the transfer of cargos from and to ships.

**S-401 Geo Feature: Harbour Basin (hrbbsn) ©**

**Super Type:**

**Primitives:** surface

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

Inland specific encoding instructions:

- A) A harbour basin is bordered by shoreline constructions and the entrance to the basin.
- B) EUR: If the ISRS Location Code is available it has to be encoded (refer to 2.4.13). If a maritime MRN or RIS-ID is available, the attribute **interoperability identifier** must be encoded (refer to **Fehler! Verweisquelle konnte nicht gefunden werden.**).
- C) EUR: Harbour Basins must be encoded.

hrbare Harbour Area (see 16.16)  
hrbbsn Harbour Basin (this page)  
prtare Port Area (see 8.27)

## 8.26 Lock Basin Part

**IHO Definition:** A lock basin is divided into several lock basin parts, if this lock basin has one ground level but several gates.

| -                     | <b>Additional Information</b> (see clause 25.1)                    | <b>Contact Details, Non-Standard Working Day, Service Hours, Nautical Information, Time Schedule In General</b> | Association | 0,*          |
| -                     | <b>Spatial Association</b> (see clause 25.11)                      | <b>Spatial Quality</b>                                                                                          | Association | 0,*          |

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

### Inland specific encoding instructions:

- A) If a lock basin has more than two gates and the ground level is the same, different lock basin parts must be created.
- B) The feature **Lock Basin Part** (lkbspt) must be covered by a **Depth Area** (DEPARE, depare) or **Dredged Area** (DRGARE).
- C) The usable horizontal clearance of length and width are distances which are provided by the competent authority for safe navigation and must be encoded with **horizontal clearance length** (HORCLL) and **horizontal clearance width** (HORCLW).
- D) The physical length and width given by the building itself must be encoded with **horizontal length** (HORLEN) and **horizontal width** (HORWID).
- E) All features which belong to one lock must be associated to a **Lock Aggregation**.
- F) EUR: A RIS-ID is assigned to each single **Lock Basin Part** (lkbspt) and **lock basin** (lokbsn) feature and to the **Nautical Information** feature associated with the entire lock (refer to 2.4.13 and **Fehler! Verweisquelle konnte nicht gefunden werden.**).
- G) If the lock basin part has a special time schedule or special operating hours apply, the feature can be combined with a time schedule. For this purpose please refer to the **Time Schedule – In General** feature (tisdge) (24.6)
- H) If a structured external XML-file with more detailed communication information is available, the reference to the file has to be entered in the **file reference** (TXTDSC) attribute.

## 8.27 Port Area

**IHO Definition:** Apart from harbours a port includes a city or borough with accommodation and facilities for landing passengers and goods and some amount of overseas trade. A port may possess a harbour but a harbour is not necessarily a port.

## 9 Geo Features – Topographic Terms

### 9.1 Sea area/named water area

**IHO Definition: SEA AREA/NAMED WATER AREA.** A geographically defined part of the sea or other navigable waters. It may be specified within its limits by its proper name. (S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.151, November 2000).

**S-401 Geo Feature: Sea Area/Named Water Area (SEAARE) (O)**

**Primitives: Point, Surface**

| -                     | <b>Spatial Association</b> (see clause 25.10)   | <b>Spatial Quality</b>      | Association | 0,*          |

† At least one of the attributes **category of sea area** or **feature name** must be populated.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 9.1.1 Sea areas

Undersea features and sea areas in general, including intertidal areas, may be identified by their names and may be delimited by the spatial types used by other geo features (for example depth contours, coastlines). If it is required to encode these areas, this must be done using the feature **Sea Area/Named Water Area**.

Remarks:

- This feature has a use similar to that of the feature **Land Region** (see clause 5.8), but for the sea.
- A **Sea Area/Named Water Area** feature of type surface should be bounded, if possible, by existing curves used by other features (for example **Depth Contour**, **Coastline**). If necessary, however, this surface may be bounded by other curves created to close the surface, or to describe a new surface.
- **Sea Area/Named Water Area** features of type surface may overlap.
- Inactive submarine volcanos must be encoded, if required, as **Sea Area** with **category of sea area** = 56 (submarine volcano). Active submarine volcanos must be encoded, if required, using an **Obstruction** feature (see clause 13.6).
- For additional guidance on encoding geographic names, see clause 2.5.8.

Distinction: Administration Area; Depth Area; Seabed Area.

Inland specific Encoding Instructions:

- A) For river or canal names, place the point feature at or near confluences where a label is needed to distinguish adjoining waterways.
- B) A surface feature may be used if its usage will aid in reducing clutter.
- C) **Sea Area / Named Water Area** (SEAARE) surface is mandatory only at confluences of two waterways up to 2 kilometres from the confluence.
- D) Use **Sea Area / Named Water Area** (SEAARE) (P) to display the name only at the location where the point was placed. A point feature should be used if the point is always on the display when it is relevant. Use **Sea Area / Named Water Area** (SEAARE) (S) if display of name is desired along water area's entire expanse.
- E) Federal Mooring Facility
  - i) Create **Sea Area / Named Water Area** (SEAARE) (P) with **feature name** (OBJNAM) = "Federal Mooring Cell(s) / Buoy(s) / Block(s)"
  - ii) Only one **Sea Area / Named Water Area** (SEAARE) should be located at each **Dolphin, Bollard or Mooring Buoy** (MORFAC) or set of MORFACs
- F) Lock Name
  - i) US & RU: The **Sea Area / Named Water Area** (SEAARE) feature must overlay the **Depth Area** (DEPARE, depare) feature representing lock chamber. **Feature name** (OBJNAM) shall be the commonly known name of the Lock or Lock & Dam.
  - ii) EUR: The name should be encoded in the **Nautical Information** feature (see clause 24.4)
- G) Sailing Line / Recommended Track: US: A second sailing line should be used only if needed for routing through an alternate lock, or around a lock, if warranted. Primary and secondary sailing line must be distinguished with **information** (INFORM) attribute, and use of **Sea Area / Named Water Area** (SEAARE) feature for labeling.
- H) **Anchorage Area:** If the name of the anchorage is important for navigation and should be displayed without the use of the pick report, use **Sea Area / Named Water Area** (SEAARE) feature additional.
- I) US: Any important navigation notes that should always be shown on the IENC should be encoded as **Land Region** (LNDGRN) (P) on land or **Sea Area / Named Water Area** (SEAARE) (P) features in the water.

## **10 Geo Features – Tides, Currents**

### **10.1 Tidal data**

The inclusion of tidal information in Inland ECDIS or ECS is optional. As such, for IENC only tidal stream and current information is required to be encoded. The implementation of tidal models based on predictions or applications to incorporate real-time tidal observations in Inland ECDIS or ECS will be the subject of additional Product Specifications utilising the S-100 Universal Hydrographic Data Model.

## 10.2 Tidal stream – flood/ebb

**IHO Definition: TIDAL STREAM.** Approximate tidal stream rates given as discrete rate values for flood and ebb flow during springs. (Adapted from S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.173, November 2000).

For IENCs the alternating horizontal movement of water associated with the rise and fall of the tide caused by tide-producing forces. Also called tidal current.

### **S-401 Geo Feature: Tidal Stream – Flood/Ebb (TS\_FEB) (O)**

**Primitives:** Point, Surface

<sup>†</sup> Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 10.2.1 Tidal stream (flood/ebb)

The term “tidal streams” (French: “courants de marée”, US usage: “tidal currents”), is used to designate the periodical horizontal movements of the water, which are astronomical in origin. These are distinguished from “currents” (French: “courants généraux”), which are not dependent on

astronomical conditions. In practice the boatmaster experiences a combination of tidal stream and current. Tidal streams are defined by the direction towards which they flow. The terms “flood stream” and “ebb stream” are used for designating the horizontal movement of the water when the tide is respectively rising or falling. To avoid any ambiguity, in the case of streams which do not turn at about the time of local high or low water, an indication must be given of the direction towards which the stream flows.

Where data are inadequate for tabulated information (**Tidal Stream Panel Data** – see clause 10.5), or where otherwise required, single observations comprising flood and ebb directions and/or rates, preferably corresponding to maximum rates at the spring tide, should be encoded.

If it is required to encode tidal stream information that is limited to flood and ebb directions and/or values, it must be done using the feature **Tidal Stream – Flood/Ebb**.

Remarks:

- Maximum directions and rates (velocities) of tidal streams during springs, where known, must be encoded in knots or km/h using the complex attributes **orientation** and **speed**, and should be quoted to one decimal place. In rivers and estuaries where there are permanent currents caused by the flow of river water, such currents must be included in the calculation of the rate. Where the speed of the current in a river or estuary is so variable as to make it impractical to indicate a value, **speed** (sub-attribute **speed maximum**) should be populated with an empty (null) value.

Distinction: Current – Non-Gravitational; Tidal Stream Panel Data.

Inland specific Encoding Instructions:

### 10.3 Current – non-gravitational

**IHO Definition: CURRENT – NON-GRAVITATIONAL.** Any current that is caused by other than tide producing forces. (IHO Dictionary – S-32).

For IENCs **Current** is preferably indicated at high and low water conditions to aid with planning, navigation and maneuvering.

#### **S-401 Geo Feature: Current – Non-Gravitational (curent) (O)**

**Primitives: Point, Surface**

<sup>†</sup> Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **fixed date range**, at least one of the sub-attributes **date end** or **date start** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 10.3.1 Current data

The term “current(s)” in this document is used to describe water movements which are generally constant in direction, and are not dependent on astronomical conditions (that is, are non-gravitational). A current is described by the direction towards which it is running. For tidal streams, see clauses 10.2 and 10.5.

Currents occur as:

- The flow of river water in rivers and estuaries;

- Permanent flows in other restricted waters, for example İstanbul Boğazı (Bosporus);
- Permanent or seasonal oceanic currents;
- Temporary wind-induced currents.

It is particularly important to depict currents (both the main flows and permanent eddies) which could set a vessel towards dangers.

If it is required to encode a non-gravitational current, it must be done using the feature **Current – NonGravitational**.

Remarks:

- Maximum rates (velocities) of currents, where known, must be encoded in knots using the complex attributes **orientation** and **speed**, and should be quoted to one decimal place. Ideally, the minimum and maximum strengths should be quoted, where known, if the strength varies.
- In tidal waters where the flow of river water alternately reinforces the ebb tidal stream and reduces the flood, the combined effect must be encoded, where required, for the convenience of the navigator; that is, the combined current must be encoded using the features **Tidal Stream – Flood/Ebb** or **Tidal Stream Panel Data** (see clauses 10.2 and 10.5). In restricted waters where tides are negligible, the direction and/or rate of flow should be encoded using **Current – Non-Gravitational**.
- Ocean currents are permanent or seasonal, are somewhat variable in strength and direction, and generally cover broad areas. In cases where the current strength and direction are subject to seasonal variations, this should be indicated using the complex attribute **periodic date range**. This may require multiple **Current – Non-Gravitational** features with attributes populated in accordance with the seasonal variations to be coincident in the IENC. Where the direction of a current is so variable that it is not practicable to show this information, the complex attribute **orientation (orientation value)** must be populated with an empty (null) value.
- Local weather conditions can produce significant temporary wind-induced currents which cannot be charted. If there is a known hazard, for example if winds from a particular direction have been found to endanger vessels by setting them on to shoals unexpectedly, a cautionary note may be added using the feature **Caution Area** (see clause 16.11). If considered necessary, the note may refer to further information in other publications, such as Sailing Directions.

Distinction: Tidal Stream (Flood/Ebb); Tidal Stream Panel Data.

Inland specific Encoding Instructions:

- Code **Current** as a surface when information applies to a larger portion of water and provide average current values (xx.x km/h) for and name of the water level(s) for which information is available.
- Code **Current** (current) as a point feature if information is based on local measurements.
- Provide direction of impact if **Current** (current) is coded as surface feature. Provide **orientation value** (ORIENT) (360°) if **Current** (current) is coded as point feature.
- Provide values for current velocity in km/h:
  - **current velocity at high water level** (curvhw)
  - **current velocity at low water level** (curvlw)
  - **current velocity at mean water level** (curvmw)
  - **current velocity at other water level** (curvow)
- State names of water levels for which current value is provided including version identification, for example year of issue or period:
  - **name of relevant high water level** (hignam)
  - **name of relevant low water level** (lownam)
  - **name of relevant mean water level** (meanam)
  - **name of other locally relevant water level** (othnam)

## 10.4 Water turbulence

**IHO Definition: WATER TURBULENCE.** The disturbance of water caused by the interaction of any combination of waves, currents, tidal streams, wind, shoal patches and obstructions. (IHO Dictionary – S-32).

### **S-401 Geo Feature: Water Turbulence (WATTUR) (O)**

| -                     | <b>Spatial Association</b> (see clause 25.10)   | <b>Spatial Quality</b>      | Association | 0,*          |

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 10.4.1 Overfalls, races, breakers, eddies

If it is required to encode a disturbance of water, it must be done using the feature **Water Turbulence**.

##### Remarks:

- If it is required to encode a breaker over an off-lying shoal, it must be done using a **Water Turbulence** feature at the same position as the feature causing the breaker (for example **Underwater/Awash Rock**).
- A **Water Turbulence** feature of type surface must be covered by **Depth Area**, **Dredged Area** or **Unsurveyed Area** features as appropriate.

##### Distinction:

##### Inland specific Encoding Instructions:

- A) Water power supplies are producing **Water Turbulences** under water at a place where the vessels enter the locks.

## 10.5 Tidal stream panel data

| <b>IHO Definition: TIDAL STREAM PANEL DATA.</b> Approximate tidal stream characteristics given as discrete value sets at a specified interval before and/or after a high or low water. (Adapted from S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.176, November 2000). |                           |                                                        |        |               |

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

### 10.5.1 Tidal stream panels

The term “tidal streams” (French: “courants de marée”, US usage: “tidal currents”), is used to designate the periodical horizontal movements of the water, which are astronomical in origin. These are distinguished from “currents” (French: “courants généraux”), which are not dependent on astronomical conditions. In practice the navigator experiences a combination of tidal stream and current. Tidal streams are defined by the direction towards which they flow. The terms “flood stream” and “ebb stream” are used for designating the horizontal movement of the water when the tide is respectively rising or falling. To avoid any ambiguity, in the case of streams which do not turn at about the time of local high or low water, an indication must be given of the direction towards which the stream flows.

If it is required to encode the information generally shown on paper charts as a tidal stream panel and stations, it must be done using the feature **Tidal Stream Panel Data**.

Tidal stream values encoded in this way should be spring rates; that is, the tidal stream rates associated with a tidal range which is defined as the difference in height between MHWS and MLWS.

#### Remarks:

- The mandatory complex attribute **tidal stream panel values** is structured such that, in combination with attributes **station name** and **station number**, the equivalent layout of a paper chart tidal stream panel can be reproduced in an Inland ECDIS or ECS Pick Report display. An example of the encoding of a **Tidal Stream Panel Data** feature as compared to the S-57 object class **TS\_PAD** is included below:

#### S-57 Encoding: Population of attribute TS\_TSP

## 11 Geo Features – Depths

### 11.1 Generalisation of depth portrayal

When a survey or chart is reduced in scale the generalization that is required has several effects:

- a. Deeper soundings tend to be eliminated while the shoaler ones are retained for safety. Sufficient numbers of deeper soundings should be retained to show the full range of depth. This is to assist the boatmaster who uses their echo sounder to help verify their position, or the boatmaster choosing an anchorage of suitable depth.
- b. Generalization proceeds by the inclusion of shoals lying to seaward of the principal contour, and by the smoothing of severely indented contours, with the effect of pushing the contours seaward. However, as a shoal which rises steeply from deep water is much more of a hazard than one which rises gradually, the encoder must ensure that the contours are not pushed seaward unduly. If the encoder gives the impression that a boatmaster will get warning of too close an approach to the danger, by relying on their echo sounder to show gradually shoaling depth - when the danger is, in fact “steep-to” - they may seriously mislead and endanger the IENC user.
- c. With the “expansion” of shoals, described above, it may become increasingly difficult to find space on an IENC dataset to show the line of deepest soundings through a channel, or even to show a channel at all. Yet even at small optimum display scales it is important to show the usable channels and indicate their least depth. The encoder may have to make greater use of depth contours than soundings in depicting narrow channels.
- d. Even such dangers as drying rocks and islets require generalization in coastal areas. This is in recognition of the principle that, whereas they are particularly dangerous in isolation and must then be shown as precisely as possible, where they occur in groups a representative depiction is permissible, showing the outermost features as individually as space permits.

### 11.2 Representation of depth: General

Some of the principles of depth depiction are summarized below:

- a. The least depth over shoals and banks, and over sills (bars) in navigable channels, must be shown. Particular attention should also be paid to full and accurate representation of all other “critical” areas, for example on and adjacent to leading lines, controlling depths in fairways and along recommended tracks, in anchorages, alongside jetties, quays and berths and in the entrances to harbours and basins. Maximum as well as minimum depth should be shown where possible, for example to show the line of deepest water in narrow channels. However, deeper soundings on the sloping side of a bank near to the crest line should not be selected if they could give the impression that there is a deeper passage across the crest between shoaler soundings.
- b. Soundings and contours must be used to complement each other in giving a reasonable representation of the seabed, including all significant breaks of slope.
- c. The density of soundings should be determined by the type of seabed. Flat or evenly sloping areas, and banks of unconsolidated sediment, should have a minimum of soundings, fairly evenly spaced, but gradually becoming more widely spaced as the depth increases. Irregular seabed topography should be represented by a denser, and probably irregular, pattern of soundings. A steep gradient should be represented by close contours, undistorted by soundings.
- d. In changeable areas, where surveys of different dates adjoin and do not match exactly, gaps in the contours may be left to indicate the discontinuity of depth to the boatmaster.

- e. Where practicable, soundings on smaller optimum display scale IENCs should be selected from those shown on the larger optimum display scale IENCs.
- f. In areas navigable only at high water, drying heights must be selected according to the same principles as soundings.
- g. Where surveys are inadequate, it may be advisable to omit some of the standard contour lines.

### 11.3 Sounding

**IHO Definition: SOUNDING.** Measured or charted depth of water (may be a drying height), or the measurement of such a depth, which has been reduced to a vertical datum. (Adapted from IHO Dictionary – S32).

### Feature Associations

| S-401 Role            | Association Type                                | Associated to               | Type        | Multiplicity |
|-----------------------|-------------------------------------------------|-----------------------------|-------------|--------------|
| The Updated Object    | <b>Updated Information</b> (see clause 25.16)   | <b>Update Information</b>   | Association | 0,*          |
| The Position Provider | <b>Text Association</b> (see clause 25.13).     | <b>Text Placement</b>       | Composition | 0,1          |
| -                     | <b>Additional Information</b> (see clause 25.1) | <b>Nautical Information</b> | Association | 0,*          |
| -                     | <b>Spatial Association</b> (see clause 25.10)   | <b>Spatial Quality</b>      | Association | 0,*          |

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 11.3.1 Soundings

A sounding associated with a rock or coral pinnacle which is an obstruction to navigation must be encoded using the feature **Underwater/Awash Rock** with attribute **value of sounding** populated with the value of the sounding.

The geometry of soundings is held in a 3-dimensional array (latitude, longitude, depth). In the interests of efficiency, multiple soundings should be encoded in one spatial type (known as “grouping” of soundings), provided that all the spatial and geo feature attributes are common to the group and all soundings in the group are related to the same sounding datum (see clause 3.9).

As the sounding multiplication factor (CMFZ) for IENC is 10, soundings may be encoded to one decimal place of a metre. Drying soundings must be indicated by a negative value. For soundings surrounded by a danger line, see clauses 13.1 and 13.2.

Population of the attributes **quality of vertical measurement**, **reported date** and the spatial attribute **quality of horizontal measurement** are described in the Table below:

| Sounding                       | quality of horizontal measurement | quality of vertical measurement | Remarks                                                                                                |
|--------------------------------|-----------------------------------|---------------------------------|--------------------------------------------------------------------------------------------------------|
| In true position               |                                   | 1 or <undefined>                |                                                                                                        |
| Out of position on paper chart |                                   | 1 or <undefined>                | Spatial type must be encoded at the true position. There is no “sounding, out of position” in an IENC. |
| Lower reliability              | 4                                 | 4                               |                                                                                                        |

|                            |   |                  |                                                                                           |
|----------------------------|---|------------------|-------------------------------------------------------------------------------------------|
| Drying                     |   | 1 or <undefined> | Negative value                                                                            |
| Doubtful                   |   | 3                | Existence doubtful should be encoded using <b>status = 18</b>                             |
| Reported but not confirmed | 4 | 9                | If available, the year of report must be encoded using the attribute <b>reported date</b> |

**Table 11-1 – Soundings – Attribute encoding**

Remarks:

- Encoders are advised to use caution when considering encoding soundings that are shoaler than the range of depth of the surrounding depth area, as **Sounding** features will not be displayed when utilising some Inland ECDIS or ECS display settings. Where it is considered that a sounding that is shoaler than the range of depth of the surrounding depth area may be a hazard to navigation, encoders should preferably conduct further investigation of source material in order to encode additional depth contour and depth area information more relevant to the sounding. Alternatively, encoders may consider using an alternate feature (for example **Obstruction**) to encode the depth.
- The attribute **technique of vertical measurement** must only be populated for **Sounding** features if it is different from the value of **technique of vertical measurement** encoded on an overlapping **Quality of Survey** feature (see clause 3.11); and the information is considered to be important to navigation.
- Where **Sounding** features are covered by the Meta feature **Quality of Survey**, the attribute **quality of vertical measurement** must not be populated unless different from the value of **quality of vertical measurement** populated for the **Quality of Survey**.
- An instance of the information type **Spatial Quality** (see clause 24.5.1) may be associated to the sounding geometry, using the association **Spatial Association** to indicate, where required, that the horizontal position and/or the vertical uncertainty for the sounding(s) is of different (higher or lower) accuracy than indicated by the underlying **Quality of Bathymetric Data** Meta feature (see clause 3.8). See also clause 3.8.1.3 (Sounding uncertainty).
- Where a named isolated shoal is indicated in the dataset by a single encoded sounding, the name of the shoal must be encoded, where required, using the complex attribute **feature name** on the **Sounding** feature. Where the named isolated shoal is indicated by two or more soundings (and possibly other submerged features), the name of the shoal must be encoded, where required, using a **Sea Area/Named Water Area** feature (see clauses 2.5.8 and 9.1).
- Encoders must exercise caution when using the option to group soundings; particularly where they are included in an IENC Update as this may impact negatively on Inland ECDIS or ECS performance regarding boatmaster interrogation of Updates. When grouping soundings in an IENC dataset, creation of excessively large sounding groups should be avoided so as to reduce the impact when a sounding is to be removed by IENC Update; and new soundings to be added by IENC Update should not be added to already existing sounding groups.

Distinction: Depth Area; Obstruction; Underwater/Awash Rock; Wreck.

Inland specific Encoding Instructions:

- Soundings** should be used sparingly in IENC, especially on rivers and canals. On rivers and canals only in rare cases where such information is of vital interest to boatmasters and no other encoding seems to be possible (like e.g. wrecks or obstructions to navigation) soundings may be used. This might be in case of isolated rocks below low water level.
- Soundings** shall always be referred to the same water level as the surrounding depth information.

## 11.4 Dredged area

IHO Definition: **DREDGED AREA.** An area of the bottom of a body of water which has been deepened by dredging. (IHO Dictionary – S-32).

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 11.4.1 Dredged areas

If it is required to encode dredged areas, this must be done using the feature **Dredged Area**.

##### Remarks:

- The attribute **depth range minimum value** must be used to encode the dredged depth for the dredged area. Where required, the attribute **depth range maximum depth** must be used to encode the deeper depth where a range of depths for the dredged area is indicated on the source.
- The boundary of a dredged area should not have coincident curve geo features encoded, unless part of the boundary corresponds to the shoreline (see clause 5.3.1).
- Dredged areas are often subject to siltation, resulting in shoaler depths being identified in the dredged area than the designed dredged depth. Where required, the shoal depths should be encoded using **Sounding**, with the appropriate underlying depth information (**Depth Area** and, if required, **Depth Contour**) to support the depths. Alternatively, the attribute **depth range maximum value** for the **Dredged Area** may be set to the designed dredged depth for the dredged area, and the attribute **depth range minimum value** set to the value of the shoalest depth, or a **Caution Area** feature may be encoded covering the shoaler depth area with the depth information provided using the complex attribute **information** (see clause 2.4.6). Where the shoal depths are close to the edge of the dredged area, the dredged area limit may be adjusted to exclude the shoal depths from the surface.
- The attribute **source date** may be used to encode the year of the latest control survey for dredged areas where the dredged depth is not maintained. For dredged areas where the dredged depth is maintained, it is not required to indicate the year of dredging.
- Where the complex attribute **vertical uncertainty** is populated for a **Dredged Area** feature, it must not be equivalent to or degrade the uncertainty indicated by the complex attribute **vertical uncertainty** for the underlying **Quality of Bathymetric Data** Meta feature (see clauses 3.8 and 24.5).
- For additional guidance regarding the encoding of vessel speed limits, see clause 17.4.
- **Dredged Area** features are part of the Skin of the Earth.

Distinction: Depth Area; Dumping Ground.

##### Inland specific Encoding Instructions:

- A) All navigable water bodies shall be covered by either **Depth Area** (DEPARE, depare) see 11.6, **Dredged Area** (DRGARE) see 11.4 or **Unsurveyed Area** (UNSARE) see 11.8 (Group 1) features.

## 11.5 Depth contour

**IHO Definition: DEPTH CONTOUR.** A line connecting points of equal water depth which is sometimes significantly displaced outside of soundings, symbols, and other chart detail for clarity as well as generalization. Depth contours, therefore, often represent an approximate location of the line of equal depth as related to the surveyed line delineated on the source. (IHO Dictionary – S-32).

For IENCs a line of constant depth denoting the depth between Shallow Depth and Fairway / Project Depth

### Feature Associations

| S-401 Role         | Association Type                                | Associated to               | Type        | Multiplicity |
|--------------------|-------------------------------------------------|-----------------------------|-------------|--------------|
| The Updated Object | <b>Updated Information</b> (see clause 25.16)   | <b>Update Information</b>   | Association | 0,*          |
| -                  | <b>Additional Information</b> (see clause 25.1) | <b>Nautical Information</b> | Association | 0,*          |
| -                  | <b>Spatial Association</b> (see clause 25.10)   | <b>Spatial Quality</b>      | Association | 0,*          |

† For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

### 11.5.1 Depth contours

**Figure 11-2 – Depth contours**

The boundary of a drying rocky area or coral reef may be coincident with the zero metre contour (see 'fg' in the Figure). If it is required to encode this boundary, it must be done using the feature **Depth Contour** with the attribute **value of depth contour** = 0.

On the source, the presentation of contours in areas of steep slope is sometimes generalised so that closely spaced contours are removed to leave a single contour (see 'ab' in Figure). In such cases, this contour must be encoded using the shallowest depth of the slope.

Wherever possible, contours must be closed, or connected to the border of the dataset, a coastline feature or another contour, in order to define closed areas.

Spatial quality associated with contours may be encoded using the **Spatial Quality** information type, attribute **quality of horizontal measurement** (see clause 28.15). This should only be encoded if the spatial quality of the contour(s) is different to that indicated for the overall quality of the bathymetric data in the area as described for the underlying **Quality of Bathymetric Data** meta feature (see clause 3.8). However, in order to provide an additional indication to the boatmaster of areas of lower reliability bathymetric data, contours in depths of 30 metres or less may have the attribute **quality of horizontal measurement** on the associated **Spatial Quality** information type populated with value 4 (approximate).

Remarks:

- Encoded drying contours must be indicated by negative values for the attribute value of depth contour.

Distinction: Coastline; Depth Area; Sounding.

Inland specific Encoding Instructions:

- A) US: USACE shall show a single **Depth Contour** for project depth (typically 2.74 (9')). A zero (0) **Depth Contour** shall also be used if a Low / High Water Range (Drying Height) exists (refer to 11.6).
- B) EUR: **Depth Contours** shall be encoded between different **Depth Areas** to allow the Inland ECDIS or ECS to highlight the safety depth selected by the boatmaster.

## 11.6 Depth area

**IHO Definition: DEPTH AREA.** A water area whose depth is within a defined range of values. (S-57 Edition 3.1, Appendix A – Chapter 1, Page 1.51, November 2000).

For IENCs detailed depth information (surface)

– either referred to one reference water level only: water surface within the waterway whose detailed depth information is within a defined range of values that refer to only one **vertical datum**, the reference water level. or

– referred to a water level model that is applied to **Depth Areas**: a water surface within the waterway in which detailed depth information is known within a defined range of values referenced to a **vertical datum** (the reference water level). The actual water level is provided by a water level model.

† For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

#### 11.6.1 Depth areas

The sea area, the intertidal area and the navigable parts of rivers, lakes and canals must be divided into depth areas, each of them having a range of depth.

As many depth areas as possible must be created using encoded depth contours.

#### Remarks:

- **Depth Area** features are part of the Skin of the Earth.

#### 11.6.2 Geometry of depth areas

Where surfaces are not closed on the source, it may be necessary to close these surfaces using edges without associated curve features. This is mandatory at the boundary of a dataset (see Figure 11-3 below).

In Figure 11-3 below, the annotation “**min**” equates to the attribute **depth range minimum value** and the annotation “**max**” equates to the attribute **depth range maximum value**.

**Figure 11-3 – Geometry of depth areas**

**Remarks:**

For short isolated sections of **Depth Contour** features such as (fi), it is up to the producing authority whether to encode the small areas (efije and fghif) as separate **Depth Area** features, or to encode only the curve (fi) as a floating **Depth Contour** feature within a single **Depth Area** (abcda) having attributes **depth range minimum value** = 5 and **depth range maximum value** = 20.

**NOTE:** In Figure 11-3, if the optional **Depth Area** features are encoded, the depth area (abcda) will be split into two separate **Depth Area** features (abgea) and (jhcdj), both having **depth range minimum value** = 5 and **depth range maximum value** = 20.

### 11.6.3 Use of attributes depth range minimum value and depth range maximum value for depth areas in general

For each depth area, **depth range minimum value** and **depth range maximum value** should be encoded with the values corresponding to the shallowest and deepest depths in that area. These values, except for the shallowest and deepest areas, should be chosen from the values of the depth contours encoded in the dataset, however the values for isolated shallow or deep areas may be taken from the shallowest or deepest measured depth (see items 2 and 3 in Figure 11-4 below).

A drying area, within which a drying height is indicated without a true position, should be encoded using a **Depth Area** feature, with **depth range minimum value** set to the value of the drying height and **depth range maximum value** set to a dataset contour value (usually zero). Alternatively, **depth range minimum value** for the **Depth Area** may be set to  $-H$  (see NOTE (a) associated with Figure 11-4 below for definition of  $H$ ), with the drying height encoded using the complex attribute **information** (see clause 2.4.6), sub-attribute **text** (for example Dries 1.4).

If a depth area is adjacent to a non-navigable waterway, a closing curve (that is, no curve geo feature) should be encoded at the boundary between navigable and non-navigable waters. See clause 11.6.4. In Figure 11-4 below, the annotation “min” equates to the attribute **depth range minimum value** and the annotation “max” equates to the attribute **depth range maximum value**.

**Figure 11-4 – Depth areas**

**NOTE (a):** H = Height of the coastline datum above sounding datum, or a rounded value (for example (1) the value of the highest drying contour indicated on the source document; or (2) zero, if the shoreline datum is the same as the sounding datum).

In the following clauses, the paragraph numbers refer to the item numbers in Figure 11-4. These clauses do not cover all encoding scenarios.

1. If the depth area is bounded by two or more depth contours:

- **depth range minimum value** should take the value of the dataset depth contour immediately shallower than the value of **depth range maximum value**.
- **depth range maximum value** should take the value of the deepest depth contour bounding the area.

2. If the depth area is only bounded by one depth contour and the deepest depth is shown by a depth contour, and the shallowest depth is shown by a sounding (an isolated shoal area):

- **depth range minimum value** should take the value of the dataset depth contour immediately shallower than the value of the sounding or  $-H$ . However if the shallowest sounding within the area is considered to be the least depth of the shoal, **depth range minimum value** may be populated with the value of this sounding.

- **depth range maximum value** should take the value of the depth contour.

NOTE: In the case where the shallowest depth in the area is equal to the bounding depth contour, both depth range minimum value and depth range maximum value may be populated with the value of the depth contour.

3. If the depth area is only bounded by one depth contour and the deepest depth is shown by a sounding and the shallowest depth is shown by a depth contour (an isolated deep area):

- **depth range minimum value** should take the value of the depth contour.
- **depth range maximum value** should take the value of the dataset depth contour immediately deeper than or equal to the value of the sounding. However if the deepest sounding within the area is considered to be the deepest depth of the deep, **depth range maximum value** may be populated with the value of this sounding.

4. If the shallowest depth is defined by the shoreline:

- **depth range minimum value** should take the value of -H.
- **depth range maximum value** should take the value of the shallowest dataset depth contour bounding the area.

5. If the depth area is bounded by only one depth contour, contains no soundings, and is a shoal:

- **depth range minimum value** should take the value of the dataset depth contour immediately shallower than the value of the depth contour, or -H.
- **depth range maximum value** should take the value of the depth contour.

6. If the depth area is bounded by only one depth contour, contains no soundings, and is a deep:

- **depth range minimum value** should take the value of the depth contour.
- **depth range maximum value** should take the value of the standard depth contour immediately deeper than the value of the depth contour.

7. If the depth area is bounded by an incomplete depth contour on one side (such as in incompletely surveyed area), and a complete depth contour on the other:

- These areas are optional. See clause 11.6.2 above and associated Figure 11-3.

8. If the depth area is bounded by complete depth contours, but contains an incomplete (floating) depth contour:

- **depth range minimum value** should take the value of the shallowest depth contour.
- **depth range maximum value** should take the value of the deepest depth contour.

NOTE: Where the optional depth areas in paragraph 7 above are encoded, this will result in two discrete **Depth Area** features, one on each side of the encoded optional depth areas. See clause 11.6.2 above and associated Figure 11-3.

#### 11.6.4 Rivers, canals, lakes, basins, locks

Where these areas are navigable at the optimum display scale for the IENC data, they must be encoded using the Skin of the Earth features **Depth Area**, **Dredged Area** or **Unsurveyed Area**, and coastline-type features **Coastline** or **Shoreline Construction**. If it is required to encode the nature and name of the area, it must be done using the feature **Sea Area/Named Water Area**.

Where these areas are required and are not navigable at the optimum display scale for the IENC data, they must be encoded using the features **River**, **Canal** or **Lake**. These features must be covered by **Land Area** features.

### 11.6.5 Areas of continual change

If it is required to encode an area of continually changing bathymetry, it must be done by populating the attribute **category of temporal variation** = 2 (likely to change and significant shoaling expected) or 3 (likely to change but significant shoaling not expected) for the underlying **Quality of Bathymetric Data** feature (see clause 3.8).

Such areas must always overlap **Depth Area** features.

An area on the source with the indication "Less water" should be encoded using the feature **Caution Area** (see clause 16.11). Caution notes in such areas must be encoded using the complex attribute **information** (see clause 2.4.6).

If it is required to encode sandwaves, this must be done using the feature **Sandwave** (see clause 12.4).

Distinction: Depth Contour; Dredged Area; Obstruction; Sea Area/Named Water Area; Sounding; Unsurveyed Area; Wreck.

#### Inland specific Encoding Instructions:

- A) All navigable water bodies shall be covered by either **Depth Area** (DEPARE, depare) see 11.6, **Dredged Area** (DRGARE) see 11.4 or **Unsurveyed Area** (UNSARE) see 11.8 (Group 1) features.
- B) The reference water level is only provided in the cell header (field: DSPM, subfield SDAT) or in the meta feature **Sonding Datum** (m\_sdat) plus attribute **vertical datum** (verdat), if applicable (e.g., within a cell where two rivers with different reference water levels meet). **Vertical datum** (VERDAT) on individual features related to depth is prohibited.
- C) Shallow depth areas with a diameter less than 10 m have to be encoded additionally as **Underwater Rock, Wreck or Obstruction** (see 13.4 Rocks, 13.5 Wrecks or 13.6 Obstructions).
- D) Detailed Depth - referenced to one water level
  - i) If the shallowest depth of an unsurveyed area near the shore is defined by the river bank and the position of the riverbank is not exactly known, **depth range minimum value** (DRVAL1) = height of the riverbank above sounding/vertical datum, normally it is "unknown". **Depth range maximum value** (DRVAL2) takes the value of the deepest **Depth Contour** bounding the area. **Quality of vertical measurement** (QUASOU) has to be encoded (see 3.11 and 11.8).
  - ii) If the shallowest depth of an unsurveyed area near the shore is defined by the river bank and the position of the river bank is exactly known, **depth range minimum value** (DRVAL1) = "0". **Depth range maximum value** (DRVAL2) takes the value of the deepest **Depth Contour** bounding the area. Drying areas have to be encoded according to D) (low/high water range) **quality of vertical measurement** (QUASOU) has to be encoded (see 3.11 and 11.8).
- E) Detailed Depth - water level model
  - i) The following encoding instructions must only be followed if a water level model shall be applied to the **Depth Areas**.
  - ii) Cut the **Depth Areas** at defined waterway profiles in order to be able to assign a **waterway distance** to the **Depth Area**.
  - iii) If the shallowest depth of an unsurveyed area near the shore is defined by the river bank and the position of the riverbank is not exactly known, DRVAL1 = height of the riverbank

- above sounding/vertical datum, normally it is “unknown”. DRVAL2 takes the value of the deepest depth contour bounding the area. QUASOU has to be encoded (see C.1.7 and I.1.9).
- iv) If the shallowest depth of an unsurveyed area near the shore is defined by the river bank and the position of the river bank is exactly known, DRVAL1 = “0”. DRVAL2 takes the value of the deepest depth contour bounding the area. Drying areas have to be encoded according to I.1.6 (low/high water range). QUASOU has to be encoded (see C.1.7 and I.1.9).
  - v) Add the attribute **elevation 1 of surface (m)** (eleva1) which is corresponding to **depth range minimum value** (DRVAL1), if it is needed for the water level model. **Elevation 1 of surface (m)** (eleva1) is used to define the maximum elevation of the bottom of a river referred to a **reference gravitational level** (reflev).
  - vi) Add the attribute **elevation 2 of surface (m)** (eleva2) which is corresponding to **depth range maximum value** (DRVAL2), if it is needed for the water level model. **Elevation 2 of surface (m)** (eleva2) is used to define the minimum elevation of the bottom of a river referred to a **reference gravitational level** (reflev).
  - vii) Add the attribute **waterway distance** (WTWDIS) with the value of the waterway distance of the downstream situated waterway profile. Do this in order to calculate the values for **elevation 1 of surface (m)** (eleva1) and **elevation 2 of surface (m)** (eleva2) automatically out of **depth range minimum value** (DRVAL1) and **depth range maximum value** (DRVAL2) (which are referred to the reference water level whose height above the **reference gravitational level** (reflev) is stored in the attribute **height** (HEIGHT) of the downstream situated feature **Waterway Profile** (wtwprf). (See **Waterway Profile** 15.25)
  - viii) If the actual water level, that is provided by a water level model, is also referred to the same gravitational reference level, one can link the **Depth Areas** with the actual water level using **elevation 1 of surface (m)** (eleva1) and **elevation 2 of surface (m)** (eleva2).
- F) Fairway Depth / Project Depth
- i) This coding method for depth is only a minimum requirement for displaying the official water depth of the fairway that is available for the continuous navigation. If more detailed depth information is available use “Detailed Depth – ref. to one reference water level “ or “Det. Depth - water level model”.
  - ii) The **Depth Area** shares the geometry of the **Fairway** with the **depth range minimum value** (DRVAL1) = official water depth in metres issued by the competent authority. The **depth range maximum value** (DRVAL2) has to be set to “unknown”.
  - iii) US: **depth range minimum value** (DRVAL1) = 2.7 (equivalent to typical project depths for vast majority of shallow draft projects) and **depth range maximum value** (DRVAL2) = “unknown” if value is not known.
  - iv) US: A Shallow Depth area or unsurveyed area must form the boundary between the Project Depth and the land, unless **Depth Area** (DEPARE, depare) is within the lock chamber.
  - v) EUR: On each side of the **Fairway** there must be a **Depth Area** between the shoreline and the boundary of the fairway with **depth range minimum value** (DRVAL1) = “unknown” and **depth range maximum value** (DRVAL2) = official water depth in metres issued by the competent authority.
  - vi) EUR: **quality of vertical measurement** (QUASOU) = 10 (maintained depth) or 11 (depth not regularly maintained) should be used to indicate the reliability of the depth information due to the legal status of the fairway.
- G) Low / High Water Range (Drying Height)
- i) Surface should border the shoreline and top bank.
  - ii) In case of tidal influence, use -H, where -H is height of tide
  - iii) US: **information** (INFORM) is mandatory: “Range between low and high water conditions”
- H) Shallow Depth

- i) US: Encode the **Depth Area** between the **Shoreline** (COALNE) and the project depth area ; **depth range minimum value** (DRVAL1 = 0) and **depth range maximum value** (DRVAL2) = 2.7
- l) The feature **Lock Basin** (lokbsn) and **Lock Basin Part** (lkbspt) must be covered by a **Depth Area** (DEPARE, depare).

## 11.7 Areas with inadequate depth information

### 11.7.1 Inadequately surveyed areas

Inadequately surveyed areas may be defined as those areas where bathymetry is based on older lead line surveys or other surveys which are either open in nature (for example reconnaissance surveys), or are not hydrographic surveys (for example seismic surveys). These types of surveys are inadequate for identifying all shoals that may exist between lines of soundings, or may not be “shoalbiased” in their selection of recorded depths.

An inadequately surveyed area should be encoded using either an **Unsurveyed Area** feature, within which soundings and contours may be encoded (but not depth areas), or using **Depth Area** features. The attributes **depth range minimum value** and **depth range maximum value** for such depth areas should have explicit values.

The area must also be covered by **Quality of Bathymetric Data** features (see clause 3.8), having appropriate attribute values, usually **category of temporal variation** = 6 (unassessed), **features detected (significant features detected)** = *False*, and **full seafloor coverage achieved** = *False*. Further information may be given using the Meta feature **Quality of Survey** (see clause 3.11), where appropriate.

A cautionary note should also be encoded using a **Caution Area** feature of type surface (see clause 16.11), complex attribute **information** (see clause 2.4.6).

### 11.7.2 Bathymetry in areas of minimal depiction of detail on paper charts

Where areas of little or no depth information exist within a specified IENC usage, they should be encoded using one of the following options:

#### 11.7.2.1 Areas of omitted bathymetry

Encoders are advised that when encoding areas of bathymetry from paper charts containing minimal depth detail at scales that correspond to the optimum display scale for the data, to consult larger scale paper charts or optimum display scale IENC datasets and generalise the bathymetry from this data. This is done to ensure that sufficient information is encoded so as not to conflict with larger optimum display scale coverage. The following is the recommended minimum encoding requirement in such cases:

Where larger optimum display scale IENC coverage is available, the larger scale datasets should be examined to determine the shallowest **Depth Area** feature, other than the intertidal area, within the whole of the area. Intertidal areas should then be generalised from the larger optimum display scale coverage, and one **Depth Area** feature may then be created, with attributes **depth range minimum value** and **depth range maximum value** encoded from the values obtained from the larger scale, corresponding to the remaining area of bathymetry.

Where larger optimum display scale coverage does not exist, a single **Depth Area** feature may be created to cover the area of omitted bathymetry. The **depth range minimum value** of the **Depth Area** feature should be set to the shallowest value appropriate to the colour tint that is applied to it (for example if blue tint is used for 5-20m areas, the **depth range minimum value** for the area of omitted bathymetry should be set to 5). The **depth range maximum value** should be set to the shallowest value of the surrounding Skin of the Earth polygons.

In either case, the areas should be covered by a **Caution Area** feature, the boundary of which follows exactly the surrounding Skin of the Earth features (see clause 2.5.3.2).

Encoders should consider the effect of over-generalising areas of omitted bathymetry on the Inland ECDIS or ECS display as the boatmaster “zooms out” through the IENC display scales.

#### 11.7.2.2 Areas of very simplified bathymetry

In these areas, information relating to bathymetry (for example depth contours, dangers, rocky areas, isolated rocks, nature of the seabed, dredged areas, unsurveyed areas) should be individually encoded as normal.

A **Caution Area** feature (see clause 16.11) should be created covering the **Depth Area** features within the area of simplified bathymetry, with a cautionary note encoded using the complex attribute **information** (see clause 2.4.6).

#### 11.7.3 Depth discontinuities between surveys

Depth discontinuities between adjoining or overlapping source bathymetric surveys may be caused by:

- Surveys in areas of continually changing depth (see clause 11.6.5) conducted with a significant time gap between the surveys; or
- Adjoining areas having significant differences in the quality of bathymetric data (see clause 3.8).

It may not be possible to safely resolve significant depth discontinuity by interpolating approximate depth contours, which may compromise the ability for the compiler to adequately encode complete, non-overlapping Skin of the Earth coverage of the area of the IENC cell covered by data. Where it is required to indicate these significant depth discontinuities, it should be done by encoding a “very narrow” **Unsurveyed Area** feature.

The “very narrow area” should be at least 0.3 mm in width at optimum display scale for the IENC data.

##### Remarks:

- An indication of the purpose of the **Unsurveyed Area** may be done by population of the complex attribute **information** (see clause 2.4.6), sub-attribute **text**, for example *Discontinuity between surveys*.
- In order to provide an indication to the boatmaster of the more reliable encoded bathymetry in an area of continually changing depth, the defining attributes should be downgraded for the **Quality of Bathymetric Data** feature (see clause 3.8) corresponding to the less reliable (or older) data.

#### 11.7.4 Satellite imagery as source information

In some areas source information may be limited to shallow water depth information derived from satellite imagery. Where defined depths can be interpolated from satellite imagery (for example the drying line, 5 metre or 10 metre depth contours), and little or no reliable source survey information exists in the area, consideration should be given to showing this information in IENCs.

If it is required to encode shoal areas which have been derived from satellite imagery, **Depth Area** and **Depth Contour** features of an appropriate depth range should be used. This should only be done in areas which have not been systematically surveyed. Areas of depth information derived from satellite imagery must be covered by **Quality of Bathymetric Data** Meta features (see clause 3.8). Recommended attribute values for the **Quality of Bathymetric Data** include **category of temporal variation** = 6 (unassessed);

**features detected (significant features detected)** = *False*; and **full seafloor coverage achieved** = *False*. Optionally, the area may also be covered by a **Quality of Survey** feature (see clause 3.11), having attribute **technique of vertical measurement** = *11* (satellite imagery).

In some cases satellite imagery provides evidence that existing charted information derived from source survey data has changed over time. If required, the attribute **category of temporal variation** on the underlying **Quality of Bathymetric Data** Meta feature should be amended to 2 (likely to change and significant shoaling expected) or 3 (likely to change but significant shoaling not expected). Alternatively, if the quality of the charted bathymetry is considered by the producer to be poor, consideration may be given to replacing the existing charted detail using the satellite derived data, as described above, however with **category of temporal variation** = 2 (likely to change and significant shoaling expected) or 3 (likely to change but significant shoaling not expected).

## 11.8 Unsurveyed area

**IHO Definition:** **UNSURVEYED AREA.** An area where hydrographic survey data is non-existent. (IHO Dictionary – S-32).

### **S-401 Geo Feature:** Unsurveyed Area (UNSARE) (C)

#### **Primitives:** Surface

### Feature Associations

| S-401 Role         | Association Type                                | Associated to               | Type        | Multiplicity |
|--------------------|-------------------------------------------------|-----------------------------|-------------|--------------|
| The Updated Object | <b>Updated Information</b> (see clause 25.16)   | <b>Update Information</b>   | Association | 0,*          |
| -                  | <b>Additional Information</b> (see clause 25.1) | <b>Nautical Information</b> | Association | 0,*          |
| -                  | <b>Spatial Association</b> (see clause 25.10)   | <b>Spatial Quality</b>      | Association | 0,*          |

† For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

### 11.8.1 Unsurveyed areas

Unsurveyed areas may be defined as those within which there is no available data derived from a systematic hydrographic survey. This may include areas which only have lines of passage soundings and/or other miscellaneous data such as isolated ship's reports.

Areas with little or no bathymetric survey information must be encoded using the feature **Unsurveyed Area**.

The area must also be covered, where required, by **Quality of Bathymetric Data** features (see clause 3.8), with attributes **category of temporal variation** = 6 (unassessed), **data assessment** = 1 (assessed), **features detected** (**least depth of detected features measured** and **significant features detected**) = *False* and **full seafloor coverage achieved** = *False*; and (if encoded on **Quality of Bathymetric Data**) **horizontal position uncertainty** (**uncertainty fixed**) = [empty (null)] and **vertical uncertainty** (**uncertainty fixed**) = [empty (null)]. If encoded on an instance of the information type **Spatial Quality** (see clause 24.5) associated to the **Quality of Bathymetric Data**, the horizontal position and vertical accuracies must be encoded as attributes **horizontal position uncertainty** (**uncertainty fixed**) = [empty (null)] and **vertical uncertainty** (**uncertainty fixed**) = [empty (null)].

#### Remarks:

- **Unsurveyed Area** features are part of the Skin of the Earth.
- **Unsurveyed Area** features containing no depth data or bathymetry are not required to be covered by **Quality of Bathymetric Data** features (see clause 3.8).

#### Distinction:

Inland specific encoding instructions:

- Those areas in the river which cannot be surveyed, for example, due to depths too shallow for surveying boats and hence no depth data is available, shall be coded by **Unsurveyed Area** (UNSARE). This shall only be done for areas below the specific water level to which the depth of the river is referred. For areas above this specific water level, **Depth Area** (DEPARE, depare) with **depth range maximum value** (DRVAL2) = 0 shall be used (refer to 11.6).
- Especially in case parts of the navigable water area are not surveyed but may be deep enough for navigation, **Depth Area** (DEPARE, depare) with **quality of vertical measurement** (QUASOU) = 2 (depth unknown) or 8 (value reported (not surveyed)) shall be used in order to show that ships may navigate in these areas as well. This may imply especially for sidearms or private marinas.
- All navigable water bodies shall be covered by either **Depth Area** (DEPARE, depare) 11.6, **Dredged Area** (DRGARE) 11.4 or **Unsurveyed Area** (UNSARE) 11.8 (Group 1) features.

## 12 Geo Features – Nature of the Seabed

### 12.1 Seabed area

**IHO Definition: SEABED AREA.** A region of the seabed including the material of which it is composed and its physical characteristics. Also called nature of bottom, character (or characteristics) of the bottom, or quality of the bottom. (Adapted from IHO Dictionary – S-32).

#### **S-401 Geo Feature: Seabed Area (SBDARE) (O)**

† Complex attribute **feature name**, sub-attribute **name usage** is mandatory if the name is intended to be displayed when display of names is enabled by the boatmaster. See clause 2.5.8.

For each instance of **surface characteristics**, at least one of the sub-attributes **nature of surface** or **nature of surface – qualifying terms** must be populated.

For each instance of **information**, at least one of the sub-attributes **file reference** or **text** must be populated.

#### 12.1.1 Description of the seabed

The nature (quality) of the seabed (bottom) must be shown in sufficient detail, where known and on the appropriate optimum display scale IENC data, for such purposes as:

- to give some guidance on holding characteristics when anchoring;
- to help in assessing the stability of shoals and to distinguish rocks from unconsolidated material, when navigating in shoal areas;
- to show where vessels may safely take the ground at low water in tidal areas; or
- to give an indication of the nature of the seabed in deeper waters for fishermen and submariners.

If it is required to encode an area of the sea where the nature of the seabed is homogeneous, it must be done using the feature **Seabed Area**.

#### Remarks:

- Generally, it is not possible to define a seabed area by its real extent, due to seabed samples usually being obtained at discrete locations. For that reason, the characteristics of the seabed area may be represented at one single position.
- Where the seabed comprises a mixture of material, **surface characteristics** must be populated as multiple iterations, with the main constituent given first.
- Where the seabed comprises layered material that is of relevance to navigation or anchoring, **surface characteristics** must be populated as multiple iterations, with the surface constituent given first, with a value for the attribute **underlying layer** of 0. Successive layers below the surface must have **underlying layer** set to 1, 2, ... .

**Figure 12-1 – Seabed areas**

In the following clauses, the paragraph prefixes refer to the examples shown in Figure 12-1.

- (a) Mixed natures: The dominant nature of the seabed (**nature of surface**) should be populated first, along with its associated qualifying term (**nature of surface – qualifying terms**), if required, using the complex attribute **surface characteristics**. Other natures should then be populated, in order of dominance, using further ordered instances of **surface characteristics**,
- (b) Underlying material: Should be encoded in the same way as mixed natures, and populating the subattribute **underlying layer** with the appropriate level of the layer below the surface layer. The surface layer must be encoded first, followed by the underlying layers.
- (c) Coral reef, which is always covered, represented as a surface: An **Obstruction** feature of type surface must be encoded with attributes **category of obstruction** = 6 (foul area), **nature of surface** = 14 (coral) and **water level effect** = 3 (always underwater/submerged). This feature must be covered by a **Depth Area** or **Unsurveyed Area** feature as appropriate. In this area, some point dangers may be shown. An **Underwater/Awash Rock** feature should be encoded for each individual point danger, with **nature of surface** = 14 (coral).
- (d) Hard bottom: The attribute **nature of surface – qualifying terms** = 10 (hard) should be encoded, with the associated **nature of surface** populated with an empty (null) value.
- (e) On the source, in the intertidal area or along the drying line, the nature of surface is sometimes shown by an open line rather than a closed area. In such cases, a **Seabed Area** feature of type curve should be encoded, with attribute **water level effect** = 4 (covers and uncovers).

- (f) If it is required to encode a rock pinnacle which is dangerous to navigation, it must be done using the feature **Underwater/Awash Rock**, while a rocky nature of seabed should be encoded using a **Seabed Area** feature.
- (g) Where a **Seabed Area** feature of type surface is located in an intertidal area, it should be encoded with **water level effect** = 4 (covers and uncovers), in order for the intertidal rock or coral symbol to be displayed in Inland ECDIS or ECS.
- The nature of the seabed should be shown in depths of 2000 m and less. The nature of the seabed may be shown in greater depths if thought to be useful.

Table 12-1 below contains the most common encoding combinations of **nature of surface** and **nature of surface – qualifying terms**; other coding combinations are possible.

| - Qualifying Terms | 1 fine | 2 medium | 3 coarse | 4 broken | 5 sticky | 6 soft | 7 stiff | 8 volcanic | 9 calcareous | 10 hard |
|--------------------|--------|----------|----------|----------|----------|--------|---------|------------|--------------|---------|
| Nature of Surface  |        |          |          |          |          |        |         |            |              |         |
